TUESDAY (8th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.
LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abrham: Pityriasis Rosea.
ROYAL INSTITUTION.—3 P.M. Dr. E. H. Starling: The Heart and its Work.
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 30 P.M. Dr. Tooth: Clinical Demonstration.
WEDNESDAY (9th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Air.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Mansell Moullin: Gynæcological Cases.
HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Habershon: Fibroid Disease of the Lungs.
THURSDAY (10th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3 30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Bacteriology of the Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. Green: Clinical Lecture.
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square).—5.30 P.M. Dr. T. D. Savill: Neuroses of the Skin.
FRIDAY (11th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.)—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.
LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Typhoid Fever and Diphtheria.
NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Beevor: Examination of Muscles.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

CAN WALL-PAPER BE RENDERED IMPERVIOUS TO DISEASE GERMS?

DR. FRANTZ has recently introduced a preparation for coating wall-papers which renders them quite impervious, and therefore capable of being thoroughly washed, even with disinfectants, without damage. The object is certainly one of importance, as existing methods of disinfection in this respect are not satisfactory. The removal of the paper may involve much expense, and sulphur fumigation blackens the guildings. A paper coated with shellac has already been used, but it is very expensive and liable to crack. Dr. Frantz's preparation is stated to be a mixture of vegetable gums which is sold under the name of the Paradox Sanitary Wall-paper Finish. It is readily applied with a brush, and does not affect the colouring or lustre of the paper. He claims for it the advantages of being devoid of smell, elastic (so that it will not crack), inexpensive, and lasting. On this last point we have nothing but the assurance of the inventor in a matter which time alone can determine. However, the object appears to be a feasible one to which he has done a service in calling attention.

Cosmos.—We cannot print our correspondent's question without knowing the reason for which the address is required.

J. S. has omitted to supply his name and address.

MEDICAL PRACTICE IN SOUTH AFRICA.

WE learn from the *African Critic* that fifty-seven fresh medical men applied for registration and licence in South Africa last year. If this rate continues the profession will soon be as overstocked there as it is in England. It is not the first time that we have issued the warning to practitioners that is implied in the above information. There are openings, and good ones, in South Africa, but they are not too numerous, and not suitable for persons unable to rough it or desirous of taking their wives and children with them. There is a career; but the career has to be carved out. It is not ready made.

L.R.C.P., &c.—The possible situation is a very hard one, but we cannot suggest a remedy as long as our correspondent's questions are based upon assumption. If he can absolutely prove that one of his patients taking his prescription to the druggist was advised by the druggist to employ another medical man, and did so, an action might conceivably lie. But the exact circumstances when they arise must dictate an answer.

"THE PUBLIC HEALTH EXAMINATION AT CAMBRIDGE."

To the Editors of THE LANCET.

SIRS,—Your correspondents "N. D." and "W. T." bring various charges against those responsible for the examination. May I point out to "N. D." that the present regulations state that all candidates who were qualified after a certain date must have done six months' practical laboratory work. The practical examination is therefore arranged to test this work, and although certain candidates are not required to be signed up, they must expect to be treated as if they have had the necessary training. "W. T." complains of the inefficiency of the apparatus provided in the gas and water analysis. He says: "The test solutions were not all the strength ordinarily used in laboratories." Perhaps not, but each bottle of standard solution bore a label on which was written the strength of the solution; a little arithmetic goes a long way in quantitative work. As "W. T." knew that only three hours were allowed for the analysis, I am astounded that he should have wasted the time even to ask for a 2 ft. tube; nor can I imagine why he should have wanted to heat more than one evaporating basin at one time. The lack of burettes of which he speaks was, when I was examined, conspicuous only by its absence. I feel sure that had he asked either of the examiners for a further supply he could have had them. If a candidate can only do one thing at a time and is unable to proceed with any part of the analysis whilst waiting for a particular reagent or piece of apparatus, I should advise him either to take a course of instruction or to keep away from the examination. That it is never so easy to make an analysis in an examination room as in a private laboratory is self-evident; but my experience is that justice is done to the practical knowledge as well as to the practical ignorance of the candidate. I am, Sirs, yours truly,

May 28th, 1897. EXAMINER.

J. S. K.—There is no restriction on practice, but it is not open to all possessors of foreign qualifications to register.

A. B. C.—The best books are Sully's "Outlines of Psychology" and Ziehen's "Introduction to Physiological Psychology."

THE SAINT MARGARET WHITE WOOL UNDERWEAR.

WE have received from Messrs Cooper, Corah and Sons of Leicester some specimens of a new ventilated woollen underwear which has been designed with the special object of ministering to the needs of the cyclist and golfer. We have placed the articles where they would obtain practical trial and have received a favourable report upon their merits. We are informed that the garments are very comfortable to wear, absorbing the perspiration and giving well to the movements of the body. The material is woven in three qualities, so that the athlete is able to suit his tastes or need with regard to the weight of the garment. It cannot be said that the material of which the underwear is made is unshrinkable, but it stands the test of washing fairly well.

A CARD FOR FRAMING THE PRINCE OF WALES'S HOSPITAL STAMPS.

FOR the possessors of these stamps who are not stamp collectors a card has been prepared with spaces in which the stamps may be placed, surrounded by the arms of Great Britain, the Indian Empire, and the principal colonies. It is published by W. S. Lincoln, 2, Holles-street, London, W., and can be obtained from him or from any bookseller, price 1*s.*

A CHILD'S AUTHORITY.

A CASE which the National Society for the Prevention of Cruelty to Children will probably take to a higher court was heard at Hove last week. A sister was summoned by the society for a common assault on a child whose stepmother had already been convicted of cruelty. The evidence was fairly clear, but the magistrates, on the ground that the child had not in so many words given the inspector authority to act on her behalf, dismissed the information.

Hosted by Google

SMITH'S DAY BOOK.

A NEW day book, designed for medical men, has been brought out by Messrs. Pitcher and Co., 4, Newman-street, London, W. It is called Smith's Day Book by its inventor, and is a handy and well-arranged book. The amount paid or credited can be seen at a glance, and no trouble is required to keep the book in order. It is a mistake to have reserved a column for "Diagnosis" on the same page as the cash account, as cash accounts might have to be inspected in a court of law or by an auditor, but the difficulty thus created can be got over by the use of hieroglyphics.

BOTANY AND THE MEDICAL CURRICULUM.

To the Editors of THE LANCET.

SIRS,—The only way in which a medical man can proclaim his wrongs and grievances is through medical journals, and as medical students have no such journal I beg to ask you to allow me a short space in THE LANCET. All I want to do is to point out the absolute absurdity of including the subjects of botany and physics in the first professional examination. Perhaps some readers will say a knowledge of botany is essential for materia medica. Well, we would not object to studying those parts which pertain to this interesting subject; but why should we be asked to learn a lot of useless stuff for three months and forget all we know in three weeks? With regard to physics, I am sure you will agree with me when I say it is of no good at all; but if the Council insist on it it ought most decidedly to be included in the preliminary examination. When we come up to the University we wish to study those subjects which pertain to medicine, and not subjects which have to do with engineering, science, and arts. Here we have Professor Tait lecturing on the properties of matter for six weeks and only devoting three weeks to sound, light, heat, and electricity, which subjects the learned Council say are of the most importance. Well, I cannot ask you to allow me any more space, but I beg of you to publish this letter and sincerely hope others more eloquent than myself will write.

I am, Sirs, yours faithfully,

May 26th, 1897. MEDICAL STUDENT.

A REQUEST.

To the Editors of THE LANCET.

SIRS,—May I through the medium of your valuable paper request your readers, if they should meet with an abortion in the earlier weeks of pregnancy, to kindly forward to me at the address given below the ovum for physiological purposes. I should be very grateful, and would willingly pay the carriage for such. The best medium for preservation is Müller's fluid; but one more commonly at hand, and which answers the purpose almost as well, is a dilute solution of perchloride of mercury.

I am, Sirs, yours truly,

GILBERT KEMPE, M.D. Durh.

Endless-street, Salisbury, May 27th, 1897.

A CASE OF QUADRUPLETS.

A CORRESPONDENT, writing from Bordighera, informs us that on May 27th a German woman married to an Italian in that town gave birth in her third confinement to three girls and one boy. The four children were alive at the date of the letter (May 30th) and were said to be all well developed.

"AN UNUSUALLY HEAVY HEART."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of to-day's date, page 1466, Dr. Reid reports a case in which the heart weighed 41 oz., and remarks that he can find only two cases in which this weight was exceeded. In Section 769: 6 of the "Medical Digest" many instances of far greater weights are recorded. I am, Sirs, yours obediently,

RICHARD NEALE, M.D. Lond.

Boundary-road, South Hampstead, N.W., May 29th, 1897.

THE PREVALENCE OF THE UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—In his Oration on the Medical Society of London in the Eighteenth Century, published in THE LANCET of May 22nd, Mr. Owen, speaking of the unqualified assistant of the present day, says: "Fortunately he is now a thing of the past, the General Council of Medical Education having sent him on a mission to minister to the necessities of the dodo and the great auk." The leaders of the profession are not always aware of the real state of things amongst the rank and file throughout the country. I do not exaggerate in the least when I say that I can show Mr. Owen hundreds of unqualified assistants doing a large share of the work of extensive practices. In my own immediate neighbourhood, which is a good and purely agricultural one, two of my medical brethren, both doing good-class practices, employ unqualified assistants, who do a large share of their work. In one case the assistant lives about four miles from the principal and does his work quite independently. Until the General Medical Council appoints officials to see that its work is done this sort of thing will flourish, for who cares voluntarily and without hope of reward to allocate to himself the functions of a private detective? I am, Sirs, your obedient servant,

June 1st, 1897. COUNTRY SURGEON.

COMPENSATION BY THE CARDIFF HEALTH COMMITTEE.

A MILK VENDOR at Roath applied to the Cardiff Health Committee for £22 compensation. The applicant stated that one of his children was suffering from fever, and he was therefore forbidden to sell milk, and consequently lost his trade. The committee decided to recommend the Council to pay the man £20.

"THE CAUSATION OF SEX."

To the Editors of THE LANCET.

SIRS,—It has always seemed to me that the various theories advanced for explaining causation of sex merely rival each other in being physiologically untenable. The fact that the theory propounded by Mr. J. F. Chambers in the *Stock-keeper* of Jan. 8th was thought worthy of annotation in THE LANCET of Jan. 30th is the immediate cause of my sending this note. I have not been able to assure myself that the theory it supports is new, but I have neither seen nor heard it advanced. It, however, seems to me to be so simple and so theoretically perfect that I am doubtful of its newness, though satisfied that if it throws no new light on the subject I shall at least be supporting a hypothesis which accords with the fundamental principles of physiology.

No doubt it originally required some stretching of faith to believe that a small cell, a spermatozoon, is possessed of the inherent property of combining with another small cell, an ovum, to undergo collective division into many cells, which ultimately arrange themselves to form a particular kind of animal—that this particular kind of animal would not only be stamped by the characteristics peculiar to the individual organism from which each germ-cell was derived, but that often it would possess peculiarities, mental or physical, undoubtedly handed down from some remote ancestor of its immediate parent or parents. It seems to me that little or no further stretch of faith is required for believing that each germ-cell is possessed of the still further inherent property of sex. In other words, it not only seems conceivable, but almost incontrovertible, that each spermatozoon is a male or a female spermatozoon, and is capable of taking part in the formation of only a male or a female animal as the case may be; and that each germinal vesicle is a male or a female germinal vesicle, and is capable of taking part in the formation of only a male or a female animal; and that a male spermatozoon cannot fertilise any but a male germinal vesicle, and a female spermatozoon cannot fertilise any but a female germinal vesicle. That is to say, unless a male spermatozoon combines with a male germinal vesicle, or a female spermatozoon combines with a female germinal vesicle, impregnation does not take place. I fancy that there are no human hermaphrodites so true as to controvert this last. Whether more proof or more disproof of this theory can be obtained from an exhaustive inquiry into twin births it would be difficult to say. Although not an obstetrician, I have had personal knowledge of two cases of twin births which lend it support. In one case the twins were boy and girl and had distinct placentæ and each a perfect set of membranes. In the other case the twins were of the same sex, and had a common placenta, though two cords, and a common bag of membranes.

I am, Sirs, yours faithfully,

June 1st, 1897. J. LOCKHART GIBSON, M.D. Edin., M.R.C.S. Eng.

"AN OBSTINATE CASE OF ECZEMA: SUGGESTIONS WANTED."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Alamuddin's inquiry in THE LANCET of May 29th I would suggest the use of a solution of Jeyes' creolin, from 2 to 10 per cent., beginning with the lower and gradually going to the higher strength as it appears to suit the case. If there is much irritation it will be well to mix with it about an equal quantity of the distilled extract of hamamelis, or, if preferred, the more expensive preparation, hazeline. This lotion should be well applied night and morning, but it would be better to keep the affected part constantly moist. A case of eczema of five years' duration obviously requires perseverance in treatment.

I am, Sirs, yours truly,

Colwyn Bay, June 1st, 1897. HENRY SIMPSON, M.D. Lond.

During the week marked copies of the following newspapers have been received:—*Essex Times, Le Figaro (Paris), Worcester Herald, Brighton Gazette, Devon Weekly Times, Manchester Guardian, New Zealand Herald, Huddersfield Chronicle, Leicester Post, Times of India, Pioneer Mail, East Anglian Daily Times, Birmingham Gazette, Western Morning News, Newcastle Leader, Architect, Rugby Advertiser, Liverpool Daily Post, Northampton Mercury, Bath Chronicle, Westminster News, Builder, Forfar Herald, Glasgow Evening News, Scotsman, Daily Mail, Bristol Mercury, Carlisle Express, Somerset County Herald, Croydon Guardian, Eastern Post, Leeds Mercury, Herne Bay Argus, Dover Express, Le Figaro, North Wales Chronicle, Knowle Journal, Yorkshire Post, Sussex Daily News, Herald of Wales, Hastings News, Oxford Journal, Derby Daily Mail, Grimsby News, Wolverhampton Chronicle, Burnley Express, Lincoln Gazette, Chatham News, Glossop Times, Preston Herald, Mona's Herald (Douglas), Mining Journal, Sanitary Record, Local Government Chronicle, Reading Mercury, Weekly Free Press and Aberdeen Herald, City Press, Educational Times, Surrey Advertiser, Crieff Journal, Citizen (Gloucester), Local Government Journal, Bury Free Press, West Middlesex Herald, Public Health, Witney Gazette, Lowestoft Standard, Darwen News, West Kent Advertiser, &c., &c.*

An Address

ON THE

PROGRESS OF SURGERY AND THE TREATMENT OF SIMPLE FRACTURES.

Delivered before the Medical Society of Swansea on March 26th, 1897,

BY A. PEARCE GOULD, M.S. LOND., F.R.C.S. ENG.,

SURGEON TO THE MIDDLESEX HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—I realise that you have conferred upon me a great and wholly undeserved honour in asking me to address you to-day, and when I recall the names of my distinguished predecessors in this office I am appalled at the serious responsibility I have incurred in accepting your kind invitation. I will not abuse your patience by vain apologies and excuses, but rather at once throw myself upon your generosity, and hope that the kindness which prompted the invitation will be extended to me throughout the address.

A surgeon to-day need have no lack of material for an address, for we who have reached and passed what has been called "the old age of youth and the youth of old age" have witnessed the rise and progress of the greatest and most beneficent advance in the art of surgery that the world has ever known. We have lived in the full flood-tide of surgical progress, and have been witnesses of a widespread change in nearly the whole of surgical practice. But I fear it is true that the treatment of simple fractures is but little better or more successful to-day than it was a generation ago, and for that reason I have ventured to choose it as my topic for this address, conscious, also, that what I say will be judged by those who have far better opportunities than I of estimating its truth and worth. The great recent change in surgical practice has not consisted merely or even chiefly in the adoption of new methods of treatment for old; such changes have been many, but they are only the outward and visible signs of the inward change in the aim, the thought, and in the very spirit of surgeons. By some this has been called a revolution in surgery—a grand upheaval, a *bouleversement*. I prefer, in spite of my critics, still to call it an evolution—the working out of the great root inspiration of all surgical art. Revolutions are not big with progress, prosperity, security, permanence; they are destructive, reversible, and opposed to the very essence of scientific progress; they are cataclysmic, volcanic. Evolution, on the other hand, is the silent, peaceful working out of the great primeval design; its steps are all forwards on the road to fullest truth; its results are irreversible. What if this change has been wrought in a single lifetime—largely by one single life—instead of being slowly and laboriously brought about by centuries? May not one day be as a thousand years?

In an address to the Medical Society of London two years ago I dwelt upon what appeared to me to be the great features of this recent evolution in surgery, and I must not be tempted into going over that ground again, fascinating as it is to me. But I want to draw your attention to three points in it, and then to show you, if I can, their application to the treatment of simple fracture. My first point is that surgeons have come to have a far higher standard by which to judge of their work than they ever had before. *Our aim is higher*, and we are all conscious of a blessed discontent with results that our fathers were well satisfied with. In nearly all directions we see the influence of this idea. The surgeon is no longer chiefly busied with lopping off useless or dangerous members, stepping in only when Nature has obviously failed, content merely to save life or relieve acute suffering. He rightly regards himself as the co-worker with Nature, whose highest duty is to complement the *vis medicatrix naturæ*, and he is satisfied only when his patients leave his hands sound and strong. Our aim to-day is our patients' cure, not recovery only, the re-establishment of perfect physical well-being, and to a large extent we are able to attain this. My second point is that surgeons nowadays recognise a heavy personal responsibility for the results of their work in the cases submitted to them. Although the surgeon's lot is a happier one to-day than ever before, because of the nearly uniform afebrile course of wounds and the speedy and painless convalescence of his patients, it is yet a fact that at no previous time has he borne so heavy a load of personal responsibility. This has come, not only from the prodigious development of the surgical art and the consequent difficulty of keeping abreast of it, but chiefly because the surgeon knows that it very usually depends upon his management of the case whether it ends well or ill. This surgical responsibility is largely a new thing, and should be never absent from our minds. It is twofold. In the first place, the work that will for ever be associated with the great name of Lister—one of the very greatest in the annals of humanity—has compelled us to make sure that our interference shall not be the means of introducing into the tissues of the body any of those potent pathogenic organisms that were the bane of surgical practice. In the second place, while we have been learning so much of Nature's power, we have come to understand the limitations of the *vis medicatrix naturæ*, and we have therefore learned both what we cannot and need not do, and what it is urgently necessary that we should do to help our patients. We have come to see more clearly that surgical art is to be, not only the ally of nature, but her complement, meeting her limitations. For instance, if we no longer speak of our treatment healing a wound, and our ointments, lotions, and potions are fast sinking into deserved neglect, it is because we know that nature does all the healing, and to her alone do we give the credit. The duty of the surgeon is to protect the body from external and accidental malignant influences, by means at once effectual and innocuous. Everywhere this rule holds good; we have to learn what nature does, and what she cannot do, where her powers are thwarted and how supported, and then the surgeon has to step in and help, taking care that it is aid and not injury that he gives. The more clearly we see our duty thus the greater becomes our responsibility. For let us not think that this is giving the surgeon's work a subsidiary place; in reality, it exalts it, his function is more limited than we thought, but in this limited sphere it is indispensable, nature cannot do our part of the task, and if we stand aside when haply by our timely aid nature might accomplish her curative task we incur a very grave responsibility.

And this brings me to my third point, which is *the very different position that surgical operations have come to occupy*. A surgical operation used to be a dangerous weapon in the hands of the most expert and skilled practitioner, and even such an one did well to hold his hand unless the necessity were well established and the attendant risks reduced to the minimum. To-day a well-planned and carefully executed surgical operation is almost a harmless procedure, and therefore to withhold its use where its success is even possible is to fail in our duty.

The recent great development of the operative side of surgical practice is due, not only to its extension to every part and organ of the body, but also to two other influences. With the safety that now attends an operation it is employed very largely indeed to obtain quickly a result that would otherwise be brought about slowly, or to obtain a better result than we could get by non-operative methods. Operations of choice or of convenience now form a very large proportion of our work, while formerly they were few, looked upon by many with grave suspicion and certainly involved the surgeon in great responsibility. Able to render assistance unattended by the terrible evils that formerly everywhere dogged his steps, he looks upon his proper work as not merely to act where unaided nature wholly fails in the conflict with disease and injury, but to assist, hasten, and improve by his art where nature largely succeeds. Closely allied to this is another factor in the great extension of operative surgery. An operation was in former times only justified when it was shown to be necessary or useful as a therapeutic measure—a mode of treatment. To-day we have such confidence in the safety of our methods that we feel justified in even resorting to the knife to gain a more perfect knowledge of our cases and to enable us to arrive at an accurate diagnosis. Diagnostic or exploratory operations are very largely resorted to, and form quite an important part of surgical practice, and it may be worth our while to discuss for a moment their scope and value.

An exploratory operation, if we use that word in its fullest significance, is of course no novelty in surgery. To

Hosted by Google

pass a probe along a wound or sinus is an exploratory operation, and to examine the bladder or uterus with a sound most certainly is. One of the glories of medicine is the fact that one after another of the great forces of nature, and one by one our sense organs, have been made our servants in the exploration of disease, and each addition to our physical methods of examination has added greatly to our diagnostic powers. Think for a moment what we owe to percussion, to auscultation, to the microscope, the ophthalmoscope and laryngoscope, to the thermometer and to the electric battery. But the exploratory operations I am referring to just now are cutting operations, the type of which is an exploratory laparotomy. I would submit that such operations are only to be approved (1) when the information they afford—an accurate diagnosis—cannot be arrived at by non-operative methods; and (2) when there is reason to believe that the exploratory operation may be converted into a therapeutic one. An exploration merely for the sake of gaining more accurate information about a case without hope of practical advantage for the patient is not justifiable, nor are such operations as can only be compared to what our legal friends would call "fishing inquiries." I am afraid we cannot in fairness deny that there has been, and is, some tendency to perform diagnostic operations without the two essential justifications I have mentioned. The ease, the painlessness, and the safety of operations, the great familiarity of surgeons with the use of the knife in all parts of the body, and the charm of a clear ocular or tactile demonstration, cannot but influence us powerfully, and if unwatched or unchecked may readily lead us astray. When it has been suggested that it is as vain to attempt to make an exact diagnosis of intra-abdominal conditions without laparotomy as it is to guess what wood a table is made of until the covering cloth has been removed, am I wrong in uttering a caution, or even in protesting that diagnostic operations must only be undertaken under the sanction of distinct and binding rules? I am anxious to put in a plea with you for the most careful, exact, and painstaking pre-operation examination of our patients. I am conscious myself, and I think I have seen it in others, of the tendency to shirk this when the case has once been shown to be one that ought to be submitted to operation. It is said, "Why waste time examining and drawing inferences about a tumour the exact conditions of which will be demonstrated at to-morrow's operation?" My answer is that time so spent is well spent in the interests of both surgeon and patient. The educational value to the surgeon himself of every effort to arrive by mental processes at an exact diagnosis is very great, and by it a mere handiworker is raised to the honourable estate of a surgeon. Again, I have been struck with this, and so must you, I am sure—that in many cases what has been demonstrated by an exploratory operation could have been definitely inferred with at least very strong probability if a sufficiently careful examination of the patient had been made beforehand and if the surgeon had had confidence in applying his knowledge. We may be sure of this—that surgery will not advance as it might unless all its practitioners train their faculties of observation and of reasoning to the highest possible pitch, and to this end make full use of the educational advantages their various cases supply. I may add, too, that some exploratory operations are very grim failures even from the surgeon's point of view; instead of clear demonstration they yield uncertainty and doubt. All riddles are not to be solved by opening the abdomen! From the patient's point of view two things may be said on this matter. 1. That an operation in itself is and always must be an evil thing, to be avoided unless its necessity or advantage is strongly probable. We none of us, I think, ever perform a negative exploration without distinct regret as well as disappointment. 2. Great elements of success in an operation are for the surgeon to recognise clearly beforehand the conditions he has to deal with, to plan out the precise steps to be taken, and to prepare to meet the particular difficulties and dangers of the case in question. The highest level of success is not attained when the operator starts with uncertain intentions and leaves his course of procedure to be determined by the exigencies of the moment. I know that this is sometimes unavoidable. I am only urging that it is a condition unfavourable to success and that we should not accept it unless forced to do so. But having said this as a plea for the most careful and painstaking examination of our patients before operation and for the cultivation to the highest possible pitch of the art of diagnosis, I must not be held to be decrying the proper use of diagnostic operations. Far from that. No one has more reason than I to know the limitations of his power of reaching without operation a distinct and accurate diagnosis in many conditions amenable to operative treatment, and the aid an open wound then affords us is very often invaluable. The regret that follows a negative exploration is, after all, much less keen than the revelation post mortem of a curable condition that a simple exploration would have revealed. In fact, it is my intention to-day to point out a direction in which I think operation may with advantage be more widely practised. And further, I think we ought to make every operation in a sense a diagnostic as well as a therapeutic measure. The tendency to error is so great that, whenever possible, the occasion of an operation should be utilised to confirm or correct our previous diagnosis, lest, proceeding upon an incorrect view, we apply an ill-adjusted remedy. Forgive me for offering to you these simple, trite reflections. The obvious is not always the most heeded! This is moreover a digression, for the point I want to make is this—that as a surgical operation has come to be very largely a harmless proceeding it is justifiably used more widely and to meet less urgent indications than was formerly the case.

I must now pass from these general observations to their application to the special subject that I wish to speak on this evening—*The Treatment of Fractures*. This is one of the most ancient branches of surgery. It is of great practical importance to the community, and as difficult as it is important, and so wide is it that it personally concerns nearly every member of the profession. Any one of these reasons would be a sufficient warrant for my choosing it as my theme to-night. But the real reason of my choice is this: the great surgical progress, in which we all rejoice, has taken place in connexion with open wounds, and the interest of surgeons has largely, almost exclusively, centred in accidental and operation wounds, and so it has come about that while there has been the greatest activity in extending the area of surgical interference by operation and in perfecting our treatment of wounds there has been no corresponding zeal shown in attempts to deal more satisfactorily with simple fractures, although they are so frequent and so grave in their results. The great stream of surgery has flowed on, ever widening and increasing in force and beneficence. But fractures have got into a quiet, almost stagnant backwater. I want to-night to drag them out of this, and to show that from our present vantage ground we can and ought to improve the treatment of fractures. It will be well for us to try to appreciate the causes that have been at work to hinder the treatment of simple fractures sharing in the great surgical revival of the last few years. Among these causes I think the first place must be given to the idea underlying the use of that word "simple." The old surgeons were right when they separated all fractures into two groups—those in which there was no wound leading from the surface of the body to the broken bone, and those in which there was such a wound. They were right, too, in expressing this difference by using such very strong terms as "simple" and "compound." We, without their terrible experience of the different results in the two classes of cases, but who have the key to the problem, and understand at any rate much of the cause of this difference, would find it difficult to fix upon words strong enough to express this difference. With the "simple" fracture were connected in the surgical mind the great ideas of safety to life, uninterrupted welding together of the broken fragments, and more or less perfect recovery. With the "compound" fracture were connected the ideas of hæmorrhage (primary and secondary), suppuration, sloughing, necrosis, blood-poisoning in its many forms, erysipelas, gangrene, greatly delayed union and often non-union, amputation, and, too often, death. Thus the accidental entirely overshadowed the fundamental, and, led away by this, the simple fracture came to be regarded as a simple injury in many senses of the word, requiring little skill in treatment, attended with little risk of functional disability, and almost a *noli me tangere*, lest the surgical "touch" should convert the harmless "simple" into the dreaded "compound" injury. As evidence of this subtle influence of a name and an idea, see how simple fractures are treated in our hospitals. I think I am correct in saying that they are almost universally handed over entirely to the house-surgeons and the dressers, and the surgeons themselves do not regard them as cases requiring their personal attention and care. The public, too, have the belief that anyone can set and treat a simple fracture, and

Hosted by Google

to fail in this is at once a demonstration of incapacity or even of malpraxis. I would submit that our error has lain in the too low ideal of excellence by which we have chosen to judge of our results and in failure to appreciate the part we have to play in the treatment of a fracture. Our standard of success or failure has too often been the firmness of the union of the fragments of bone, with, in some cases, a quite subsidiary regard for obvious deformity of the part. But the real standard by which we ought to judge our results is the perfection of function of the part. That point is very simple, and you will no doubt admit it at once, but think of the number of patients who recover from a fracture with more or less permanent impairment of the use or function of the part! How often do patients forget even on which side of a limb or of their body some extensive wound of the soft tissues was—so entirely oblivious of it are they long years afterwards! How rarely do we find anyone equally oblivious of the seat of an old fracture! We must not rest content until we obtain as perfect results in the one case as in the other. Now, this improvement will not come through any new power in nature to deal with these cases, but simply waits for us to do our part in the matter better and with more deftness and skill. Mr. Arbuthnot Lane has attempted to express the loss of function after a broken leg in terms of pounds, shillings, and pence, and he has at any rate shown that a working man's earning power—his market value—is often seriously diminished by an injury that has been repaired and that surgically seemed of secondary importance. We see, then, the application of my first point. We have to apply to the treatment of fractures the higher standard of excellence that we apply so largely elsewhere. We must aim, not at union merely, but at *perfect restoration of function*. Upon what does the perfect restoration of the function of a broken bone depend? First and foremost upon the perfect structural repair of the bone. The relation between structure and function is intimate and ultimate; we are unable to go behind it and explain it, but have to accept it. A very apt illustration of this is seen in the structure of voluntary and involuntary muscle. Chemically all but identical and developed from the same embryonic layer of cells, we might have expected that the one difference between them would be in their nervous connexions, but instead of that we find a striking difference in the intimate structure of their fibres; and the structure of heart-muscle standing intermediate between voluntary and other involuntary muscle shows us how intimate is the relationship between structure and function. We are apt to forget, I think, that this close relationship holds true of bone also. Each bone is exquisitely adapted for its special function, not only by its coarser features—its length and general contour, but also by the disposition of its compact and cancellous tissue, and even by the exact arrangement of its lamellæ; and we cannot interfere with its structure without a corresponding loss of function, and so, if we are to treat fractures well, we cannot be too deeply impressed with the absolute necessity of securing perfect structural restoration of the bone, and not merely firm union. If we ask, How is this perfect repair to be obtained? the answer is, By the bony union of fragments that have been exactly replaced in position. The part that nature takes in the repair of a fracture is the welding together of the fragments into a more or less compact and firm mass of bone, and wonderfully and beautifully is her part accomplished. Our art is here wholly powerless; we cannot replace nature; we may by meddlesome surgery impede her, but at our best we can do little, if indeed anything, actively to aid her. What nature cannot do is to restore to their correct position misplaced fragments. Art can do this—it is her chief part; and when art performs her part as perfectly as nature almost invariably does hers the result is entirely good. This, then, is the surgeon's share of the task.

I have ventured to bring from the Middlesex Hospital Museum a few specimens of old fractures, such as are to be found in all pathological collections. They are generally used as examples of the powers of nature in healing a broken bone; they show us overlapping ends of bone firmly welded together, comminuted fractures with wide separation of the fragments all united again into a solid, resisting bone; they show us, too, the opened medullary cavity securely closed over, and sharp, projecting angles rounded off. For all this they are worthy of admiration. But I have brought them down to show not as feats of nature, but as failures of the surgeon. Each of these specimens tells of a tragedy, of an useless limb, a marred and impoverished life, and all not because nature failed in her part, but because the surgeon failed in his share of their combined work. With the exception of some few cases of ununited fracture, probably also of some cases of fracture into joints and of cases of separation of epiphyses, imperfect functional results of simple fractures are due to failure on the part of the surgeon. I do not say culpable, blameworthy failure, but I want to make it clear that in no case submitted to a surgeon is his responsibility for the ultimate result greater and more direct than in the case of a broken bone. In no case are his duties more important or more necessary if perfect success is to be attained. If this is so I think I have made good my point that a surgeon ought to approach the treatment of a fracture with the same sense of great personal responsibility that he does the treatment of a wound in the soft parts. If the standard of success to strive after has been correctly stated, and if the surgeon's share in attaining it has been duly estimated, you will agree with me that fractures, even if surnamed "simple" are not trivial cases, and in many instances their treatment will tax the ability of the most gifted surgeon, and in some cases baffle all his efforts. We may, however, be sure of this—that nothing has so tended to paralyse us as a conviction—too widespread—that the difficulties presented by fractures are often insuperable, and that it is no reflection on our art to be vanquished by them. Nothing will help us to overcome these difficulties more uniformly and well than a clear appreciation of their nature, of their importance, of the great limitations of the power of nature to cope with them, and of our correspondingly great responsibility. Realising our duty and with faith in ourselves what means can we adopt? what snares avoid? 1. In the first place, we should always do our utmost to make an exact diagnosis of the condition of the bone; not merely of the fact and position of the fracture, but of the number and position of the fragments and the plane of the fracture. In arriving at this we have two great helps. The chief of them is anæsthesia. A recent fracture is a very painful injury, and the manipulation necessary for its exact diagnosis may cause great suffering. I am convinced that it is as much the surgeon's duty to give an anæsthetic to assist him in arriving at his full and exact diagnosis in such a case as in any of the more grave surgical conditions, and of course the anæsthesia which permits of the diagnosis will also greatly facilitate the proper treatment. I believe this teaching would be considered rank heresy by many, but I am convinced of its soundness. The second great aid will be afforded by the x rays and the fluorescent screen. At present this means is the luxury of the few, but the time will come, I hope, when we shall all be able to avail ourselves of its aid in the cottage of the miner as well as in the fully equipped hospital. 2. Having arrived at a full and correct diagnosis, the next point to attend to is to reduce the fragments at once, at the earliest possible moment, remembering that lapse of time always increases the difficulties in doing this, never lessens them, and soon makes them insuperable. 3. This reduction of the fragments must be complete or perfect at once; we must not rest in any halfway house, content with improvement to-day in the hope of still further correction to-morrow. Such is, I believe, an entirely bad practice and a most fruitful source of error and ultimate failure. We are all conscious of the temptation to be satisfied with less than ideal success, but here it is courting failure. I appeal to your experience, necessarily much larger than mine, whether I am not right in insisting upon this point, and whether you have not found that only when reduction is complete is the patient comfortable, and are the fragments easily retained in position. 4. This latter point is specially worth remembering. We often hear of fractures being "set," and of the fragments slipping away again. This undoubtedly occurs. But fortunately the surfaces of a fracture are nearly always uneven, or even considerably jagged; and it follows from this that when these surfaces are *really accurately fitted together they hold together;* and it is worth bearing in mind that recurrence of displacement generally means imperfect reduction, while conversely perfect replacement is in nearly all cases the greatest aid to the subsequent maintenance of the bone in the correct position during healing. The transverse fracture of the patella is of course a striking exception to this rule. 5. The means best adapted to secure this perfect adjustment of the fragments vary with different cases. The causes of the displacement are either the

Hosted by Google

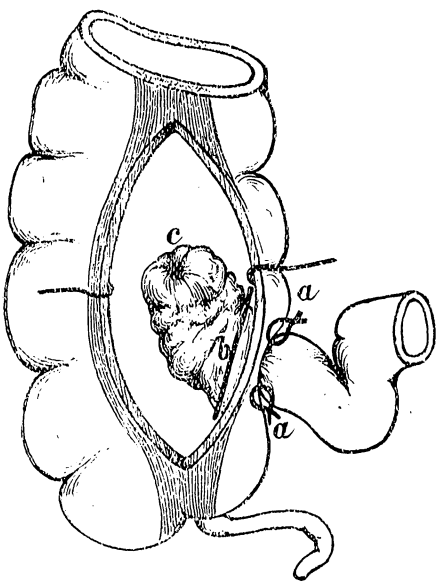
fracturing force, the action of gravity, or the pull of muscles. Success in correcting it is best attained by a careful study of each case. We should always try to overcome the action of the muscles by relaxing them, and not by opposing their pull by extension and counter-extension. For this purpose surgical anæsthesia is of the utmost value, and I am of opinion that it is used far too little both for diagnosis and treatment of fractures, and that we ought to use anæsthesia for these purposes in all but the very simplest cases. I was taught, as many of you doubtless were, that it was exceedingly bad practice under any circumstances to give an anæsthetic for the setting of a simple fracture, lest in some unconscious movement the patient should thrust the broken bone through the soft parts. I first unlearned that lesson years ago when a distinguished American surgeon came to me with a broken wrist and insisted on treatment that should certainly restore to him an agile right hand, but by painless surgery. 6. Another point I think of primary importance is to replace the fragments before applying the splints or bandages. The proper use of a splint or other retentive apparatus is to assist in keeping the broken bone immobile while nature is completing her task of uniting the fragments. For this purpose they are excellent; but whenever we trust to them to correct the displacement we are doomed to disappointment. Let me mention one or two familiar examples. Look at the very numerous apparatus for the treatment of fractures of the collar-bone, all of which are supposed to aid in forcing the fragments of the bone into their proper position. What miserable failures they all are! Whenever we are very anxious to obtain repair of this fracture without deformity we discard the whole of them and place our patient flat on his back in bed. Again, what a failure it is attempting to correct the deformity of Colles's fracture by a pistol splint, Gordon's splint, or Carr's splint? But if we first of all correct the displacement and then maintain the fragments in their proper position by resting the limb on either of these splints we at once obtain excellent results. Or, who has seen an oblique fracture of the shaft of the femur recover without any shortening by the use of a long splint and extension? The fact is that the most extraordinary ingenuity has been expended in efforts to make splints and bandages do what they are not intended to do and are not capable of doing. Failure lies that road and we must avoid it. Full success is only attained when the surgeon first reduces the displacement and then secures the part in his splint. The cases in which we fail and which give us the most anxiety are just those where we are unable to do this. 7. Into the details of splints and bandages I cannot enter; nothing is better than a well-fitting Croft's splint, and the more nearly any other splint approaches to the effect this gives the better it succeeds. Nor will I take up your time with any words on the value of passive motion, frictions, and careful use of the limb as soon as the union is strong enough to withstand the strain thus thrown upon the particular bone. For I want, in conclusion, to discuss what part operative interference may play in the treatment of fractures. Should we, or should we not, extend to fractures the same development of surgery that we have step by step extended to other injuries and diseases? Thus stated the question contains its own answer. Let us, first of all, be quite clear as to what operation can do for simple fractures: (1) it can exactly replace fragments in their proper position; and (2) it can mechanically fix them until the natural process of ossification is complete. In old ununited fractures it in addition opens up again the medulla from which the plastic callus is formed. Now, at the outset we ought to bear in mind one or two very grave considerations. 1. It goes without saying that such an operation must only be undertaken under conditions ensuring an aseptic wound. If a simple fracture is ever transformed by the surgeon into a compound fracture it must be done only when all the special evils attaching to compound fractures can be absolutely excluded. 2. The exact fitting together of the fragments may be exceedingly difficult. All fractures are not like transverse fractures of the patella; many, indeed, are worse to piece together than any Chinese puzzle. 3. And even then the difficulties are not at an end, for our surgical means of holding fragments together are imperfect and in some cases very difficult to apply. 4. In fact, except in such cases as the patella or in uncomplicated oblique fractures of the tibia these operations are of extreme physical difficulty and, like matrimony, are "not to be enterprised nor taken in hand unadvisedly, lightly, or wantonly."

My own conviction is that with due care and perseverance, particularly with the aid of an anæsthetic, the cases in which the surgeon is unable to do his duty by exact replacement and fixation of the fragments are very few. But in those few cases I think it is incumbent upon the surgeon to put to himself the question whether the difficulties he meets with can with reasonable certainty be overcome by an operation. If they can and he has all the requisite means at command it is his duty then to operate. He must be prepared to meet with considerable difficulties, and he must act with a clear and full recognition of his responsibilities. I would not for one moment advocate a general or a frequent employment of operations for simple fractures. Such a practice I hold to be needless, dangerous, and ill-advised. But, on the other hand, I am prepared to contend that when other means fail to give us that result for which we should always strive and which our patients ought to demand of us, a serious responsibility is laid upon us if we withhold from them the aid an operation may afford. I admit that here I am not on very firm ground, although I anticipate that in the future this position will in the main be generally held; but I am on quite solid ground when I plead for the general adoption of a higher standard of excellence in the repair of simple fractures and to this end urge the free use of anæsthesia and the most patient and careful efforts in their setting.

SEVEN CONSECUTIVE CASES OF INTUSSUSCEPTION IN INFANTS TREATED BY ABDOMINAL SECTION, WITH SIX RECOVERIES.

BY BERNARD PITTS, M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; LECTURER ON SURGERY TO THE MEDICAL SCHOOL, ST. THOMAS'S HOSPITAL.



THE following cases have been under my care either at the Hospital for Sick Children, Great Ormond-street, or at St. Thomas's Hospital between 1893 and the present time. No one with any experience of the treatment of intussusception would expect such a favourable record to be maintained. Some cases are almost hopeless from the first moment they are seen in hospital. A run of successful cases must depend either upon immediate treatment or the fortunate absence of severe damage to the bowel. Until the last few years it has been the practice to exhaust all other methods of treatment before abdominal section was resorted to, and it is not surprising that a successful case of surgical interference was most exceptional. Physicians, under whose care these cases are generally admitted, now employ inflation and manipulation only when the patient is in good condition and has come very early under observation, and are satisfied that abdominal exploration should be undertaken without delay if complete reduction is not at once brought about. In all the acute cases now recorded the physician in charge requested the surgeon's immediate attendance, and to this saving of valuable time the successful results must certainly be attributed. Children under one year of age are commonly supposed to be unfavourable subjects for abdominal exploration. With proper precautions, however, abdominal section may be performed without great risk from shock, but the temperature of the body must be maintained by wrapping the extremities in cotton wool, operating on a hot-water cushion, and taking care that the manipulations are carried out quickly and with great gentleness. The seven cases may be divided into two chronic and five acute. The average age of the acute cases was nine and one-fifth months. The chronic cases are of special interest, since it was necessary to incise the colon and remove irreducible bowel in each instance.

CASE 1. *Chronic intussusception (one and a half years' history); removal of intussusception through the colon.*—The patient, a male child, aged two years and three months, was admitted to the Hospital for Sick Children, Great Ormond-street, under the care of Dr. Barlow, on March 11th, 1893. The mother stated that the child was fed on the breast till the age of thirteen months. When nine months old he had a sudden attack of abdominal pain, with sickness and passage of blood with his motions. A similar attack occurred at the age

Hosted by Google

of twelve months, and a lump was then noticed on the right side of the abdomen. Since that time he had had four or five attacks of a similar character. At first the child appeared quite well between the attacks, but of late he had suffered from constipation and occasionally from diarrhœa. On the Monday before admission he was seized with pain in the abdomen, and on the Tuesday morning passed blood with his motion. The abdominal pains continued, and after two days sickness commenced. As the attack did not seem to subside the mother determined to bring the child to the hospital. On examination the patient was found to be a fairly well-nourished child with a small moveable lump in the right hypochondrium. The abdomen was not distended, the walls were flaccid, but there was some tenderness over the position of the lump. The child remained under observation and careful feeding from March 11th to the 27th, and during this fortnight had frequent attacks of pain, accompanied by sickness. Several well-formed motions were passed, but they were always streaked with blood. The abdominal lump varied considerably in size and position and could occasionally be traced for a short distance along the transverse colon. On March 20th an examination was made under chloroform and the lump could then be felt to the left of the middle line, but on manipulation seemed to lessen and to take up a position corresponding to the ascending colon. On the 27th it was, after consultation, determined to explore the abdomen as the child was losing power; the attacks of pain were more frequent; some distension of the abdomen

FIG. 1.

was now also present, and the difficulty in getting the bowels open by enemas was increasing. During the week preceding operation the temperature varied between 97° and 100° F. and the weight had fallen from 1 st. 12 lb. to 1 st. 9 lb. On the afternoon of the 27th an incision 2½ in. in length was made in the right semilunar line with its centre slightly below the level of the umbilicus. The tumour was readily brought out of the wound, and found to be an intussusception of about two inches of the ileum into the cæcum. The appendix was not engaged, and the intussusception was of the ileo-colic variety. A vertical incision two inches long was now made in the commencement of the ascending colon; the intussusception was found to be thickened and solid, resembling very much an os uteri in appearance. The mucous membrane covering it was much ulcerated, and the lumen was reduced to the size of a goose quill. Reduction was quite out of the question, and it was necessary to remove it. The ileum above the affected part was carefully stitched (Lembert's sutures) to the large bowel, and one and a half inches of intussusception were then cut away with scissors. The mucous coats were secured within the colon by interrupted silk sutures, and the lumen examined and found with a little stretching to admit the forefinger. The child stood the operation well considering its severity; his pulse, which was not good at the commencement, became feeble when chloroform had been administered for three-quarters of an hour, and ether was substituted as the anæsthetic. Fig. 1 shows the appearance when the colon was incised and the margins of the opening retracted. The temperature in the evening was 102 4°, but fell to normal on the next morning. Convalescence was steady. After the operation no more blood was passed with the motions, and the attacks of pain entirely ceased. During the following year, on several occasions the child had to be treated in hospital for constipation, which was overcome by abdominal massage and administration of salad oil. He has developed into a fine, healthy boy, and was last seen on Feb. 7th, 1897. The cicatrix was perfectly sound, the abdomen normal, and he was attending a board school. No stricture can therefore have developed at the line of resection. In this case it is probable that the intussusception which occurred at the age of nine months never completely went back, and during the next one and a half years there was a constant tendency to recurrent attacks and the gradual closure of the lumen of the intussusceptum. The hæmorrhage was explained by the ulcerated condition of the mucous membrane about the orifice of the lumen. Such a complete stenosis was not anticipated before the exploration owing to the character of the motions, which were generally well-formed. The formation must have occurred after passing the strictured bowel. The case was, in fact, thought to be one of recurring intussusception due to the probable presence of a polypus. It was only after a fortnight's observation in hospital that operation was decided upon, for it was felt that interference must be attended with considerable risk. The advantage of dealing with such a condition by resection through the colon as originally suggested by Mr. Barker is obvious, and lessened the risk of resection very greatly.

CASE 2. *Chronic ileocæcal intussusception due to a complete inversion of the appendix; removal of the appendix through the colon.*—The patient, a pale, cachetic female child, aged two and a half years, was admitted to St. Thomas's Hospital, under the care of Dr. Acland, on Jan. 13th, 1897. Three and a half months before she had been playing about on her bed, turning head-over-heels. She seemed quite well, and directly afterwards had her dinner, which she vomited, and then complained of pain in her stomach. Next day she repeatedly had spasms of pain of short duration. These attacks continued for many days. The bowels were relaxed and considerable quantities of blood and slime passed. The mother did not notice any swelling of the abdomen, but it was hard and rigid during the attacks of pain. Food was taken well without sickness. She was treated by several medical men, who diagnosed her case as one of gastric catarrh. On Dec. 29th, 1896, the mother found that her bowel had come down, and called in Dr. Ford, who found an intussusception protruding four inches beyond the anus. He could feel a tumour in the abdomen by palpation. After reducing the rectal protrusion the child was inverted and kneading of the abdomen commenced. Suddenly a gurgling sensation was felt, and the abdominal tumour entirely disappeared. Dr. Ford sent the child to St. Thomas's Hospital, and she was kept under observation till Jan. 2nd. During these few days nothing abnormal was discovered; the motions were normal and free from blood or mucus. The very day she left the hospital the pains returned, and were specially severe when walking about. On Jan. 4th the bowels were very loose, and blood and slime were again noticed with the motions. The symptoms continued till Jan. 13th, when the mother noticed that her condition was much worse. On re-admission to the hospital on the evening of the 13th Dr. Toller, the resident assistant physician, examined her under an anæsthetic, and felt a sausage-shaped tumour in the position of the transverse colon—the tumour was freely moveable—and seemed to alter in size and position. The abdomen was somewhat distended, but the child's general condition was good. At 11 P.M. she was again placed under chloroform and an incision made in the middle line just below the umbilicus. The small intestines were found to be full of fluid contents, and in the mesentery of the small bowel numerous caseous glands were to be seen about the size of cobnuts, and a few small nodules like tubercles on the mesenteric border of the bowel. The omentum was adherent to the mass of enlarged glands and the upper part of the abdomen shut off. These conditions at first suggested that

Hosted by Google

the tuberculous condition present might account for the symptoms, but as the cæcum could not be found it was thought right to explore further, and after separating the omental adhesions with some difficulty the transverse colon was reached and drawn into the wound. The presence of an intussusception in it was then discovered, and with gentle manipulation this was easily reduced. It was noticed that after apparent complete reduction no appendix was visible. At the position where it should normally be attached was seen a dimple; here also was the base of its mesenteric attachment. On examination of the cæcum an elongated swelling could be felt within it resembling a thickened appendix. A vertical incision two inches long was now made, having its centre at the junction of the cæcum and ascending colon, and a chronically thickened and completely inverted appendix was found. All attempts at reduction failed, so the appendix was cut away and its base sutured, and then further secured by stitching the peritoneal coat of the cæcum over it. The incision in the large bowel was sutured and the abdominal wound closed. The child was kept under the influence of small doses of tincture of opium. Recovery was uninterrupted, the abdominal wound healing by first intention. The last note is on February 10th. The child was quite well and in good spirits, but still kept in bed on account of the tuberculous condition discovered at the

FIG. 2.

operation. The temperature had been normal since operation. The diagram shows the appearance after reduction of the intussusception and retraction of the sides of the incision in the large bowel.

Remarks.—It is highly probable that some condition of irritation within the appendix caused it to turn inside out as the first commencement of trouble. The inverted appendix then acted as a polypus within the bowel, and produced the ileo-cæcal intussusception for which she was treated by Dr. Ford. A chronic recurrent form of intussusception followed; but fortunately no adhesion formed, and the reduction at the time of operation was easily effected. The removal of the appendix was necessary for a radical cure. It is to be hoped that as a result of the thorough examination of the abdomen, and the prolonged rest and after-treatment, that the commencing tuberculous lesion will be arrested. The group of enlarged glands were in the mesentery of the small bowel, far away from the seat of intussusception, and evidently quite unconnected with it.

The following five cases of abdominal section for acute intussusception are given very briefly.

CASE 3.—The patient, a male child, aged nine months, was admitted to the Hospital for Sick Children, Great Ormond-street, on March 11th, 1895, under the care of Dr. Penrose. He was found to be a well-nourished child with a history of being languid and out of sorts for four days. During the twenty-four hours preceding admission the child had suffered from abdominal pain; he had vomited after food and had passed three motions containing blood. On examination the abdomen was not distended, but an indefinite tumour was to be felt on the left side. Dr. Penrose saw the child at 1 P.M. on the morning of admission, and under an anæsthetic the colon was distended with warm water and the tumour seemed to disappear. As the condition of the child was not quite satisfactory, an examination under an anæsthetic was again made at 3 P.M. and a swelling detected in the splenic region. A median incision was made and an intussusception discovered and reduced after some few minutes of traction and compression. It was of the ileo-cæcal variety, a portion of the ileum with the cæcum and appendix being engaged in the colon. The bowel was very œdematous, and the chief obstacle to final reduction was the invaginated mesentery, which contained some enlarged glands. The thickened ileum after reduction was greatly indented by the pressure of these glands and showed no sign of resilience. Recovery was uninterrupted. The child was discharged well on April 24th, 1895, and was kept under medical observation for the next six months.

CASE 4.—The patient, a male child, aged one year and eight months, was admitted to the Hospital for Sick Children, Great Ormond-street, under the care of Dr. Barlow on Dec. 17th, 1895. The patient had been quite well until Nov. 30th, when, while being nursed, he stretched himself back over the arm of his nurse and tried to get free. Shortly afterwards he vomited, and again the next morning, but he did not seem to be in pain. On Dec. 1st attacks of abdominal pain commenced and blood first appeared with the motions. Sickness and attacks of pain continued up to the time of admission. On examination no distension of the abdomen could be found, but just above the umbilicus, running transversely in the direction of the transverse colon, a sausage-shaped tumour was to be felt—at times the swelling became harder to touch—and easily visible. His general condition was good, considering the many days' history of pain and sickness. In the evening, after consultation with Dr. Barlow, an incision was made in the right semilunar line. An ileo-cæcal intussusception was found and somewhat easily reduced, the chief obstacle again being the presence of enlarged mesenteric glands. Recovery after operation was perfectly satisfactory; but on Dec. 31st, when about to leave the hospital, he developed varicella, and was detained in hospital till Feb. 1st. He was re-admitted with a severe attack of diphtheria on April 10th, and discharged again on June 8th. He had remained perfectly free from any intestinal trouble, but there was a little bulging at the lower part of the operation cicatrix. Considering that definite symptoms had been present for a fortnight this case might almost be classed under the head of chronic intussusception. Great difficulty in the reduction was expected, but reduction was, in fact, easier than in any of the other cases.

CASE 5.—A male child, aged ten months, was admitted to St. Thomas's Hospital under my care on March 2nd, 1896. Three hours before admission, after vomiting a large quantity of undigested milk, the child passed blood and mucus from the bowel and was in evident distress. On admission the child was in a condition of shock. A typical tumour could be made out through the abdominal wall, and the top of the intussusception could just be felt within the rectum. Five hours after the first onset of symptoms chloroform was administered and inflation of air tried. By this means, combined with manipulation, the tumour was reduced to the middle of the transverse colon, but could be persuaded no further, so abdominal section was at once performed through the mid-line below the umbilicus. The tumour was delivered through the wound and finally reduced with great difficulty, taxis having to be employed on the gut for quite a quarter of an hour. The ileo-cæcal valve was especially œdematous. The bowels were opened regularly every day after operation, the first motion passed containing some dark blood. Recovery was completely satisfactory and the child was discharged cured on March 30th. Air inflation in this case was most fully and carefully tried and was expected to succeed, since the symptoms had only existed five hours. The reduction was the most difficult of the acute cases, and there can be little doubt that if the child had not been brought at once to hospital it would have speedily been impossible. This case

Hosted by Google

was reported in the *St. Thomas's Hospital Gazette* of March, 1896, by Mr. Abbott, together with two other successful cases by Mr. Clutton and Mr. Makins. Some of Mr. Abbott's remarks have been used in the concluding suggestions.

CASE 6.—A male child, aged ten weeks, was admitted to St. Thomas's Hospital, under the care of Dr. Acland, on Nov. 24th, 1896. The child had not passed anything by the bowel for six days—viz., since Thursday, Nov. 19th. He had been seriously ill all that time, refusing food and vomiting for two days. On examination the abdomen was found to be uniformly distended; no tumour could be felt. The finger after introduction into the rectum was covered with mucus. The pulse was very rapid, and the general condition extremely bad. After consultation with Dr. Acland it was determined to explore, and a median incision was made below the umbilicus. The small intestines were found to be greatly distended, and on the most gentle manipulation the peritoneal coat split in several places. A small incision was made into the distended small bowel, and a considerable quantity of fluid fæces were evacuated. This incision was then sutured, and on further examination an intussusception was found at the splenic flexure. The ensheathing bowel was very soft and gave way in the transverse colon. The intussusception was then seen to be in a state of gangrene. The child was in such a collapsed state that a prolonged operation was impossible, so the gangrenous intussusception was cut away with scissors through the opening in the colon, and then the aperture in the colon brought to the surface and an artificial anus established. Death took place a few hours later.

CASE 7.—A male child, aged five months, was admitted to the Hospital for Sick Children, Great Ormond-street, under the care of Dr. Barlow, on the evening of Feb. 3rd, 1897. The child was quite well on Feb. 2nd, but about 10 A.M. on the 3rd he suddenly became pale and bathed in cold sweat, and at 12 A.M. passed blood per anum, and continued to pass blood every hour until his admission. The patient was a well-nourished child; his abdomen was soft. On palpation an elongated mass in the line of the sigmoid flexure was found. Per rectum, within easy reach of the finger, a firm, rounded swelling with an elliptical orifice in the centre could be felt. As the child strained the tumour descended almost to the anus and bright blood was passed. An anæsthetic was given at 2 A.M. on Feb. 4th, fourteen hours after the first symptoms, and an attempt made to reduce the intussusception by water pressure. The tumour receded from the rectum, but no effect was produced either by inflation or manipulation on the abdominal swelling. A small median incision was then made below the umbilicus, the descending colon was brought out of the wound, and by compression and squeezing behind the swelling the intussusception was made to travel slowly upwards as far as the cæcum. It was found to be of the ileo-cæcal variety, the mesenteric glands at the junction of the small and large bowel were considerably enlarged and caused difficulty in the final reduction. The disengaged bowel was soft and inflamed. During the next twenty-four hours two motions were passed, the first containing blood. Small doses of tincture of opium were given. The child was given the breast on the next day, but unfortunately the mother's milk supply ceased, and humanised milk was substituted. Recovery was entirely satisfactory.

Remarks on the acute cases.—It will be noticed that distension of the large bowel by air or water was tried on all the patients except Cases 4 and 6. In Case 4 symptoms had been present for over fourteen days, and in Case 6 the abdomen was greatly distended and the general condition of the child contra-indicated any attempt at inflation. Symptoms had also existed for a week. Notwithstanding the very satisfactory results obtained by laparotomy in these acute cases, and the failure to completely replace the intussusception by inflation and external manipulation, it would be wrong to argue against the trial of such measures in suitable cases. The fact that many cases of acute intussusception have been cured without operation, and the supposed great danger attending abdominal exploration in very young infants, has led in the past to a too prolonged and sometimes a repeated trial of inflation. It is not possible or right from a small sequence of cases to lay down any rules applicable to all conditions, but the following statements result from my experience derived from these cases now put on record, and, unfortunately, from many unsuccessful cases of operation previously to the year 1893.

1. In cases of recent acute intussusception distension of the bowel by air or water combined with gentle external manipulation may be tried under an anæsthetic. The surgeon should, however, be *present* and prepared to at once open the abdomen if a satisfactory result is not quickly obtained. In many cases the effect of such inflation is to reduce the main mass of the tumour, but to leave an irreducible portion in the right iliac and lumbar regions. This amount of success aids the subsequent operation and allows the tumour to be easily delivered through a smaller incision and with less manipulation. Supposing that inflation has apparently been successful the child should be carefully watched, and with evidence of continued trouble abdominal section should be resorted to and no further inflation tried. (Ex. Case 3.)

2. An exploratory operation should be undertaken without preliminary inflation, when from the severity of the symptoms or the chronicity of the case there is reason to believe that such inflation would be dangerous or unlikely to succeed. It must always be remembered that the time taken up by inflation adds considerably to the shock.

3. The median incision is most suitable in the majority of cases, but when the tumour is in the cæcal region a limited incision in the right semilunar line may be found most convenient. For the reduction of the final portion of an intussusception the tumour should be brought outside the wound so that the operator may clearly see the condition of the bowel and make sure that the reduction is complete. Thickening about the ileo-cæcal valve may be easily mistaken for an incomplete reduction. When in doubt an incision may safely be made into the colon, and the parts examined from within the bowel. An incomplete reduction will certainly lead to further trouble. In some of the supposed cases of spontaneous cure, or cure by inflation or manipulation, it is highly probable that complete reduction is not effected, and the chances of recurring symptoms are therefore greater than after careful operation.

4. In none of the cases operated on by me did it seem desirable after reduction to attempt any fixation of the bowel—such as by suture of the mesentery—as a security against recurrence. Such a procedure seemed contra-indicated, since it would add to the length of the operation and must be most uncertain as to the effect produced. All the children were given small doses of tincture of opium and kept under constant medical supervision for a considerable time after convalescence from the immediate condition.

5. When reduction is found impossible a resection inside the colon would seem to afford the best chance. The junction between large and small bowel must be made secure before any part is cut away. When gangrene is present the condition in young children is almost hopeless. Complete resection and end-to-end union, whether by Murphy's button or suture, so far has been practically without success. Perhaps rapid resection, with lateral implantation of the small bowel into a healthy portion of the colon, and bringing the cut end of the large bowel to the surface as a temporary vent for the escape of flatus, would be the quickest and safest method to adopt. Safely, however, as infants stand a short operation, a prolonged one under such circumstances seems almost beyond their power.

Note.—Since the above was written, four months ago, a case of chronic intussusception in a child has been operated on by me at the Hospital for Sick Children, Great Ormond-street, but died a few hours afterwards.

Harley-street, W.

CASES OF FOLLICULAR TONSILLITIS DUE TO MILK INFECTION.

BY C. GREY-EDWARDS, B.A., M.B., B.CH. DUB.,

AND

WALTER D. SEVERN, F.C.S.,

ASSOCIATE OF THE ROYAL COLLEGE OF SCIENCE.

1. *Clinical Observations* (by Dr. C. Grey-Edwards).—On Feb. 12th last I was called to a farm to see two children and a servant. They were all sitting up, and complained of general pains about various parts of the body, headache, "chilly feelings," &c. No direct complaints were made about the throat, but my inquiries elicited that "it was a little sore." On inspection I found that the tonsils

Hosted by Google

were enlarged, red, and spotted with the soft, creamy, membranous patches typical of follicular tonsillitis. The temperature ranged from 100° to 103° F., and in each case about three days elapsed before they came down to normal. In the case of the maid there was considerable prostration and languor: she was quite unable to work for three weeks. Between Feb. 12th and 24th I attended three more cases, and four other cases occurred which I did not see. On the 20th I was called to another house and here saw a similar case of follicular tonsillitis—that of a young girl with exactly the same type of throat, whose temperature was as high as 104°. As the milk was supplied from the farm where the first cases had occurred, I recommended that all the milk used should be carefully boiled, and also that the case should be isolated as much as possible and every precaution taken to guard against a spread of the malady. On the 26th there were two fresh cases, and I then sent a specimen of some of the suspected milk to the West-end Pathological Laboratory in London for bacteriological examination. The report (exclusive of the technical detail) was as follows:—(1) Staphylococcus pyogenes aureus, present; (2) staphylococcus pyogenes albus, present; (3) streptococcus pyogenes (short form), present; (4) bacillus diphtheriæ (Klebs-Löffler), absent; and (5) bacillus tuberculosis, absent. On March 1st I saw another case from the same house, and sent a sweeping of the throat for examination. The same bacteria were found as in the milk. Three of the patients in this house had partaken of the milk, but the fourth had not, and I consider it probable that infection took place from one of the other three cases in the early stages. Three children, between the ages of two and three years, escaped altogether, owing, I believe, to the fact that their milk was invariably boiled. In addition to the above cases I was called in to one other patient with a throat of the same character, and here again the milk partaken of had been supplied from the same farm. On receiving Mr. Severn's report on the first specimen of milk I induced the farmer to have the cows examined by a veterinary surgeon, who, however, failed to detect anything wrong, and it was not until the milk from all the cows had been separately examined that the offending animal was discovered. In the milk from this cow were found the same organisms as were present in the first specimen of milk and in the sweeping from the throat.

2. *Bacteriological Evidence* (by Mr. Walter D. Severn).—It is seldom that one obtains such exactly correspondent results from bacteriological researches as have been obtained in Dr. Grey-Edwards's epidemic of follicular tonsillitis. In examining the first specimen of milk, plate and Petri dish cultivations on gelatin, agar-agar, and glycerine agar-agar were made immediately on arrival, and large surfaces of Kanthack-Stephens medium and serum were well rubbed over with heavy platinum spatulæ and incubated at 37° C. Portions of the milk were also placed in sterilised strong glass tubes and rotated on a motor centrifuge, and from the resulting deposits after treatment with ether, &c., cover-glass preparations were stained and examined for tubercle bacilli and bacillus diphtheriæ. Other cover-glass preparations stained by the Gram-Weigert method were found to contain a few organisms resembling morphologically the pyogenic cocci. Numerous short and long rod forms were also present, but most of these latter were very faintly stained. In the deposits from this specimen in addition to the epithelial débris and leucocytes of the form usually found in cows' milk, there were present true pus cells, variable in shape and dimensions, multinuclear, and fairly numerous. Staphylococcus albus was the organism which greatly predominated in the first specimen of milk; streptococcus brevis was fairly numerous; while staphylococcus aureus only appeared to the number of three very distinct small orange colonies on a plate poured from 0·2 c.c. of the milk. Of the two infected specimens of milk examined this first one was by far the richer in cocci, but it also contained rather numerous decomposition bacteria, including bacterium lactis, owing to its not having been taken with any special precautions as to sterility. The gelatin plates, which were as low as attenuations from a loopful of milk, were not rich enough in colonies of the organisms sought for, while the bacillar forms present were, even at these high dilutions, too numerous. In such cultures as could be incubated at 37° C. the temperature hastened the development of the pathogenic cocci, at the same time inhibiting the contaminating bacteria, isolation becoming fairly easy. In the case of the throat sweeping no plate cultures at all were attempted. The rather large brush which was used appeared to be somewhat dry on arrival at the laboratory, so it was moistened with sterile water and well rubbed over in the following order: (1) a large glycerine-agar surface; (2) a large plain faintly alkaline agar surface; and (3) a surface of serum. Incubation took place at 37° C., and the same organisms were found again, but only two colonies of staphylococcus albus were found. Some colonies of micrococcus citreus formed were, however, easily distinguished by the size of the cocci and by the non-liquefaction of gelatin from staphylococcus pyogenes citreus. The last specimens sent consisted of one of water from a well on the farm in question, and three different specimens of milk labeled each with the name of the cow which produced it. The water was carefully examined by plate culture and may be dismissed at once as a very good water with no suspicious feature (bacteriologically). Two of the specimens of milk were also free from suspicion. The bottles containing the milk were sterilised and the specimens were taken with certain aseptic precautions; it was probably owing to this care that in the two specimens just mentioned very few colonies indeed appeared even of aerial or putrefactive bacteria; the task of working up the colonies was thereby greatly simplified. In the milk of the third cow, which we may regard as the one to which the infection has been definitely traced, the two staphylococci and the streptococcus were again found. They were, however, apparently not so abundant as in the first specimen of milk examined, and the staphylococcus albus had almost disappeared. At a rough estimation I should think, however, that the pus was not diminished in quantity. In conclusion, I would like to emphasise the necessity and usefulness of cultures made by rubbing the surface of already cooled and set agar plates with a small quantity of milk or other suspected fluid in such examinations, in addition to the ordinary plate cultures. Agar-agar of a high melting point is sometimes very difficult to maintain sufficiently fluid throughout at a temperature which is not distinctly inhibitory to pyogenic cocci at their first critical transition to saprophytic growth. It is also necessary to make quite sure of the identity of any cocci found by morphological appearance and aggregation, by staining reactions and by careful micrometer measurement, by culture characteristics, and finally, if necessary, by inoculations.

THE ANTITOXIN TREATMENT OF DIPHTHERIA AT ST. GEORGE'S HOSPITAL.

BY CHARLES SLATER, M.B. CANTAB., &c.,
LECTURER ON BACTERIOLOGY, ST. GEORGE'S HOSPITAL;
AND
J. A. CAMERON, M.B. CANTAB., &c.,
LATE HOUSE PHYSICIAN, ST. GEORGE'S HOSPITAL.

THE treatment of diphtheria by antitoxic serum is still held to be on its trial, and therefore any results of such treatment appear worthy of record. The cases dealt with in this paper are those admitted to St. George's Hospital during the period October, 1894, to June, 1896. The injection of anti-diphtheritic serum was the routine treatment and a bacteriological diagnosis the rule; but both were subject to many exceptions. In the earlier months of the treatment the slight cases were frequently not injected. Owing to a change of registrars, due to severe illness, in 1895 the case records were for some time irregular, and it has been necessary to reject certain cases from consideration, though they would have had a favourable result on the statistics of treatment. The serum employed was in all cases that supplied by the Institute of Preventive Medicine and the seat of injection the flank or abdomen. In one case only did any septic accident occur; in this case a small abscess formed at the seat of injection, but was followed by no further ill effects. The following table shows the number of patients admitted as cases of diphtheria during the years 1891-1895, together with the first six months of 1896. The percentage of deaths and recoveries in each year is also shown. The diagnosis

Hosted by Google

throughout rests on clinical grounds, and the results of each year are strictly comparable:—

TABLE I.

Year.	Number of Admissions.	Recoveries.	Deaths.	Percentage of Recoveries.	Percentage of Deaths.
1891...	27	19	8	70·3	29·7
1892...	18	8	10	44·4	55·6
1893...	83	51	32	61·4	38·5
1894...	62	47	15	75·8	23·8
1895...	152	122	30	80·8	19 2
1896*	70	60	10	85·7	14·3

* Six months.

This table shows a great increase in the number of cases of diphtheria since 1892—an increase now well recognised—and a fall in the percentage death-rate during the last three years. This fall is coincident with the introduction of the serum treatment. The year 1892 is remarkable for the paucity of the cases and the high mortality. Of the 10 cases which died 8 were tracheotomised and only one recovered. Since October, 1894, there were admitted 241 cases with the provisional diagnosis of diphtheria, and of these 180 cases were examined bacteriologically or treated with antitoxin. The 180 cases are grouped in Table II.

TABLE II.

Bacteriological diagnosis.	Number of cases.	Number injected.	Recoveries.	Deaths.	Percentage of Deaths.
Positive	112	76	90	22	19 6
Negative	49	16	48	1	2 0
Doubtful	6	4	6	0	—
Omitted	13	13	10	3	23·0
Total	180	109	154	26	14·4

Of the 167 cases bacteriologically examined the diphtheria bacillus was found in 112 cases, or 67 per cent. The agreement between the clinical and bacteriological diagnosis is really closer than appears from these figures, as in many of the 49 in which the diagnosis was negative the examination was made as a measure of precaution; 8 of them were out-patients and never admitted. Amongst the 76 cases which were injected and in which the diagnosis was confirmed bacteriologically there were 15 deaths, or a percentage of 19 8. This percentage death-rate is practically identical with the death-rate for the total cases admitted from 1894 to June, 1896. This indicates an improvement since the introduction of the treatment, as amongst the total cases there are many which were not diphtheria; but it is impossible, owing to the previously mentioned irregularity in the records, to actually compare the figures between the treated and untreated amongst the cases in which the bacillus was found. The following table shows the death-rate in various age periods amongst the cases treated by antitoxin:—

TABLE III.

Age.	Diagnosis confirmed.			Diagnosis unconfirmed.		
	Number of cases.	Deaths.	Percentage of deaths.	Number of cases.	Deaths.	Percentage of deaths.
Under 1 year	1	0	0	—	—	—

The general opinion of the physicians employing the serum has been that the need for tracheotomy in even severe cases of laryngeal obstruction is now much less frequent than formerly. If the need did not arise immediately on admission it rarely did so later, when the serum had been used. As a result, the local treatment of the throat has become much less active.

Effect on tracheotomy.—The operation was performed thirty-five times, with 42·8 per cent. of deaths. Of 27 cases treated with antitoxin 9 died—mortality 33·3 per cent.; and of 8 not treated six died—mortality 75 per cent. Amongst the 8 untreated cases were of course some desperate ones, which nothing would have saved, but, on the other hand, 2 cases are included amongst the treated who recovered from the tracheotomy but died subsequently from paralysis. That the treatment has improved the chances of cases requiring tracheotomy is very strongly impressed on all who have had to deal with such cases, and this impression is confirmed by the above figures and a comparison with former statistics. In the three years 1891–93 there were 38 cases with 27 deaths—a mortality of 71 per cent., as compared with 33·3 per cent. amongst those treated with antitoxin. The mortality amongst the untreated cases has remained practically constant (from 71 per cent. to 75 per cent.).

The amount of serum used varied from 5 c.c. to 60 c.c. The usual quantity was 30 c.c. given in two injections—20 c.c. the first day and 10 c.c. the second. The maximum amount used at one time was 20 c.c. The date of the injections varied from the second to the ninth day of the disease. No general connexion between the date of the injection and the therapeutic result can be drawn from the figures.

Immediate effects of the injection.—The most striking effect is the rapid clearing of the throat. The charts of the cases reveal no immediate effects on the pulse, respiration, or temperature, though the period of pyrexia is materially shortened. Albumose was found in the urine in eight consecutive cases on the day following the injection. Unfortunately, this point has not been regularly investigated.

Remote effects.—These include the now well-known rashes and pains in joints. A rash of morbilliform character was seen in several cases, preceded by an urticaria lasting two or three days. Constitutional disturbance, evidenced by increased rate of pulse and respiration and rise of temperature, is by no means an uncommon accompaniment of the rash, and may precede it by several days. A rise of temperature without a rash may occur about the seventh or eighth day, this being the usual time at which the rash appears after the injection. The earliest day on which the rash was noted was the third and the latest the eighteenth. A second and even a third period of eruption and constitutional disturbance has been observed, but occurs rarely. A rise of temperature accompanied the rash in 40 per cent of the cases. Paralysis occurred in 21 of the injected cases and 6 died. Two of the fatal cases had been discharged as cured, and some of the others had also been discharged, so that it is possible that more cases of slight paralysis occurred than appears from the above numbers. In one case the bacteriological diagnosis had been negative. Albuminuria seems to have been unaffected by the treatment in either sense.

There remain to be noticed a few detached points of interest. One case of relapse or second infection occurred. A child, six years of age, was admitted with a second attack thirty-four days after her first admission. On both occasions the bacillus diphtheriæ was found. A child, apparently healthy except for a "cold" in the head, was the source of infection for two other members of the family. The nasal discharge of the *healthy* child was full of diphtheria bacilli. There was no constitutional disturbance in this child. A case in which, on post-mortem examination twenty-one hours after death, membrane was found at the cardiac end of the stomach, and from this a culture of the bacillus diphtheriæ was obtained, is of bacteriological interest.

But little confirmation was obtained in these examinations of the statements that the severity of the disease is related to morphological varieties of the associated bacillus. Such statements can only be of value if made on the basis of direct examination of the false membrane. A few cases occurred amongst patients in hospital for diseases other than diphtheria, and were characterised by the typical appearance and purity of the cultures obtained and the extreme mildness of the disease. One case was remarkable—it has been reported by Dr. Ogle[1]—in that death was caused by a small

[1] Transactions of the Pathological Society of London, 1896.

Hosted by Google

stalked papilloma growing from the healed scar of a tracheotomy wound and causing obstruction of the larynx.

With the exception of the effect on tracheotomy cases, it is impossible to draw from the above statistics any strong evidence in favour of the serum treatment; nevertheless, noting the decided improvement in the statistics of the later years, the increased success of tracheotomy, the rapid clearing of the throat after injection, and the many details not capable of being reduced to statistics, there seems no doubt that the antitoxic serum has been of great value in the treatment of diphtheria. With a greater uniformity in the strength of the serum supplied, and a more accurate knowledge of the dosage, a better result may be hoped for.

NOTES ON

TWO CASES OF TOXIC AMBLYOPIA FROM IODOFORM.

BY JAMES W. RUSSELL, M.A., M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

DURING the last two years I have treated most of my phthisical out-patients with considerable doses of iodoform, according to the system advocated by Dr. Foxwell in a paper published in the *Birmingham Medical Review* in August, 1894. As to the real value of the treatment I hope shortly to obtain some evidence by the analysis of my cases, and I may here merely say that I have hitherto firmly believed that comparatively good results are to be obtained by its means. The dose taken has varied with the circumstances of the case. Generally, unless any special contra-indication has been observed, the initial dose has been two grains three times a day, and this has been increased by two grains per dose every week, as inquiry showed the absence of toxic symptoms. From eight to ten grains has always been the maximum dose, and when this quantity has been reached constant inquiry for symptoms of poisoning has been made, and occasional intermissions in the treatment have been insisted upon. In only two cases have I observed any important symptoms of poisoning from the use of the drug, and in each of these the symptom has taken the form of a well-marked amblyopia. The following are brief notes of these cases, for part of which I am indebted to Dr. Wood White, who kindly examined the patients at the Birmingham and Midland Eye Hospital at my request.

CASE 1.—The patient, a man aged thirty-two years, came to my out-patient department on March 26th, 1896, complaining of cough, wasting, and shortness of breath of recent onset. On examination, signs of early phthisis were found at the apex of each lung. He was ordered a mixture containing cod-liver oil and iron and two-grain pills of iodoform to be taken three times a day. On April 16th he had been taking six grains three times a day for a week, and complained of a disagreeable "metallic" taste and smell; I therefore reduced the dose to four grains, and next week he reported that these symptoms had practically ceased. On May 7th the dose was increased to five grains, and from this time the quantity taken was gradually increased, without any further complaint on the part of the patient, until on June 18th ten grains were ordered to be taken three times a day. On July 9th an inquiry as to the condition of the sight elicited the fact that for the last week or two he had experienced some increasing difficulty in reading, especially at night; the iodoform was accordingly stopped and the patient was sent to the Birmingham and Midland Eye Hospital for examination. On July 20th Dr. Wood White reported that the vision of each eye was reduced to $\frac{6}{18}$. Beyond the omission of the iodoform no special treatment of the condition was adopted, but on Aug. 6th Dr. Wood White reported that the vision of each eye was $\frac{6}{9}$, and on Nov. 26th it was noted that the sight was normal.

CASE 2.—The patient, a man aged twenty-six years, first attended my out-patient department on Sept. 14th, 1895, complaining of an attack of hæmoptysis which had occurred a few days previously. He had been suffering of late from profuse night sweats; there were, however, no definite physical signs to be found in the lungs. During the next six weeks he had several further attacks of hæmoptysis, and by the end of October had developed distinct signs of phthisis at the left apex. On Sept. 28th he was ordered to take one grain of iodoform three times a day, together with a mixture containing cod-liver oil and iron. The quantity of iodoform was slowly increased, and on Nov. 2nd had reached eight grains per dose; and although I find that for some reason the dose was on Feb. 1st, 1896, reduced to six grains, yet on April 26th he was again taking eight grains, his weight having increased by eight pounds since the beginning of treatment. Shortly afterwards the dose was increased to ten grains. From this time he continued, with occasional intermissions, often of a few weeks' duration, to take varying quantities of iodoform, with apparently excellent results; but on Jan. 2nd, 1897, after having taken ten grains of iodoform for only three weeks continuously, he stated in answer to my inquiry that he had noticed of late some increasing difficulty in reading, again especially at night. The iodoform was at once stopped, and Dr. Wood White, who examined the patient at the Birmingham and Midland Eye Hospital, kindly sent me the following report of his condition: "Consensual light and accommodative reflexes present. There is no reflex on stimulation of sensory nerves in either eye. Vision: right eye, $\frac{6}{60}$, improved by + 50 cylinders; left eye, $\frac{5}{60}$; colour vision normal; right field of vision normal; left slightly contracted; discs pale, but not atrophied. The amblyopia in this case differs from that due to tobacco in that there is no central colour scotoma" After the above examination the patient failed to attend at either hospital for some time, but returned to my out-patient department early in April. He stated that his sight had rapidly recovered after leaving off the iodoform; and on testing I found that it was normal in each eye. His chest was free from signs of active mischief, and he looked and felt in good health.

The cases of toxic amblyopia from the administration of iodoform hitherto published are few in number. In a paper describing one such case, published in 1893 in the *Ophthalmic Review* by Mr. Priestley Smith, reference is made to two cases as the only ones then recorded. One of these was published by Hirschberg in 1882,[1] and resulted from the local application of iodoform; the other, recorded by Dr. E. Hutchinson,[2] was due to its internal administration. The third case, published by Mr. Priestley Smith, occurred in the out-patient practice of Dr. Foxwell at the Queen's Hospital, Birmingham, and was also caused by the use of the drug internally in considerable doses. I have been unable to discover any later addition to the literature of the subject. It is difficult to say in what proportion of cases treated with iodoform amblyopia is likely to make its appearance. Dr. Foxwell seems to regard the symptom as a very uncommon one; my cases would rather suggest, however, that when large doses are taken for any length of time it is likely to be not very infrequently met with. On referring to my case-books I find that I have notes of 187 cases in which iodoform was administered, excluding all those in which the patient attended a single time only. Of these 187 patients 20 complained of the unpleasant taste and smell to which the drug is apt to give rise; and 12 of these were taking only six grains or less at the time. Of the two patients who suffered from amblyopia only one had complained of the taste of the pills. It is to be noted, however, that in only a certain proportion of the cases did the dose reach as much as eight or ten grains; and that, moreover, a considerable number of the patients attended for but a short time only. The following table will present a summary of these points:—

Total number of patients taking over 5 grains 133					
" " 8 or 10 grains 84					
Attended over 6 months ...	4	.....	Maximum dose 10 grains		4
" from 3 to 6 months	12	.....	" " "		6
" from 6 weeks to 3 months ...	69	.....	" " "		32
" under 6 weeks ...	102	.....	" " "		5

Again, the time during which the large dose has been taken has varied considerably, 27 patients taking this dose for periods varying from four weeks to five months, with occasional intermissions, as already described. None of these patients developed any important signs of poisoning during the continuance of the large doses, but 5 complained of the smell or taste at some period of the treatment. The 2 patients who developed amblyopia had each

[1] Centralblatt für Praktische Augenheilkunde, p. 92.
[2] New York Medical Journal, Jan. 2nd, 1886.

Hosted by Google

been taking ten-grain doses for three weeks only at the time when the symptom was reported.

Since the cases above referred to, together with the two recorded in this paper, appear to establish the fact that iodoform is liable to cause amblyopia, it becomes a question whether its use internally is any longer justifiable. This question may, I think, be answered in the affirmative, always supposing that the treatment is of real value. In my own cases and in that recorded by Hirschberg, recovery was complete and rapid after the discontinuance of the iodoform; in the other two recovery was progressing satisfactorily when the last notes were taken. It therefore seems probable that if the amblyopia be early recognised and the drug promptly omitted no permanent mischief need be feared. I have now adopted the plan of recording the vision of all those patients whom I am about to treat with iodoform before beginning its administration; I then make periodical inquiries as to the sight, and am able to discover when any diminution is acknowledged whether alteration has really taken place. This measure is, I find, absolutely necessary owing to the certainty in hospital out-patient practice that any symptom frequently inquired for will sooner or later be acknowledged by the patient. I have only to add that in my cases the onset of the amblyopia was not accompanied by any other symptom.

Birmingham.

FOUR SUCCESSFUL CASES OF TRANSFUSION OF SALINE FLUID.

BY NATHAN RAW, M.D. DURH., &C.,
MEDICAL SUPERINTENDENT AND PATHOLOGIST, DUNDEE ROYAL INFIRMARY.

IN THE LANCET of Aug. 17th, 1895, I recorded six successful cases of transfusion of normal saline solution, and since that time several cases have occurred in the practice of the Dundee Royal Infirmary in which transfusion has been employed, in some with wonderful effect and in others with well-marked temporary improvement. The following is a brief note of the successful cases.

CASE 1.—A woman, aged thirty-nine years, pushed her arm through a window, severely lacerating it. She bled profusely and on admission to the infirmary an hour afterwards was in a very serious condition. She was quite unconscious and markedly anæmic; the respiration was shallow, with occasional sighing; no pulse could be detected. She had a transverse wound over the front of the left elbow-joint severing the radial artery at its origin. The median cephalic vein was also divided, and into this were transfused five pints of normal saline solution at a temperature of 105° F. The effect was very wonderful. In a few minutes she opened her eyes, consciousness slowly returned, and the pulse became quite good and regular. She made a good recovery and went home in ten days.

CASE 2.—A boy, aged twelve years, was admitted to the infirmary on March 25th, 1896, under the care of Dr. MacEwan, with extensive disease of the right knee-joint. He was in a fairly healthy condition. Dr. MacEwan excised the right knee-joint, and numerous tuberculous deposits were found in the femur and tibia, even above the epiphyseal lines. The medullary cavity of the femur was opened and drained. The patient did not suffer from shock or loss of blood, and he bore the operation well. He remained fairly well for thirty-six hours, when he suddenly developed a rigor and became delirious; his temperature was 103° F. and his pulse 144. The wound was dressed but found to be sweet. Eight hours afterwards he was quite unconscious and apparently dying. The left internal saphenous vein was opened, and four pints of saline fluid were introduced with a very good effect, as, with the exception of a severe rigor half an hour after the injection, he made a good recovery and is now almost well.

CASE 3.—A man, aged thirty-two years, had his arm caught in machinery, rupturing the brachial artery and smashing the arm. He lost a very large amount of blood and when brought to the hospital was in a very collapsed state. Amputation at the shoulder-joint was performed. He suffered from collapse, and during the night his pulse could not be felt. He was transfused with five pints of saline fluid. An hour afterwards he had a rigor, with a temperature of 103° F., but with this exception he made a rapid recovery.

CASE 4.—A woman, aged twenty-three years, was admitted on June 6th, 1896, under the care of Dr. Whyte, suffering from purpura and anæmia. She had several severe attacks of violent epistaxis which were difficult to control. The patient's condition became very serious; the pulse was quite imperceptible, and she was apparently dying. She was transfused with five pints of saline solution, with the effect noticed in Cases 2 and 3—viz., a rigor and temperature of 104° F. one hour later. She revived almost at once and made an excellent recovery.

Remarks.—There can be no doubt that we have in transfusion one of the most simple yet efficacious remedies in all cases of shock from hæmorrhage. How far it is of service in cases of nervous shock and collapse is yet undecided, but in some cases it is of great value. Larger quantities should be given than those generally recommended, four or five pints being a usual quantity. I have given as much as twenty-four pints at four injections within twenty-four hours without any apparent discomfort. I have noticed in several cases the occurrence of a rigor, commencing from half an hour to an hour after the operation and lasting about five minutes, with a high temperature. This seems to have no serious effect, the temperature quickly subsides, and recovery is not retarded by it. In Case 2 there is every reason to suppose that an acute attack of septic osteo-myelitis was cut short by the transfusion, my explanation being that an increased volume in the vessels would offer a greater resistance to attack and at the same time dilute the blood stream and so disperse the micro-organisms. If this be so, there is reason to suppose that transfusion may be employed in acute specific diseases due to micro-organisms, as in any case it could have no other than a highly beneficial effect if performed with ordinary care and with a sterilised solution. The apparatus I use consists of an ordinary glass funnel and tubing, with a glass nozzle for insertion into the vein.

Dundee.

NOTES ON THE ANATOMY, DEVELOPMENT, PATHOLOGY, AND SURGERY OF THE FRONTAL SINUSES.

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

Anatomy.—The frontal sinuses are generally two irregular cavities between the inner and outer tables of the frontal bone, near the root of the nose. In the fresh state these cavities are lined with a thin, pale, closely-adherent mucous membrane, and separated from each other by a well-marked septum. They usually communicate separately with the corresponding nasal cavity by an opening, variable in size, leading into the anterior extremity of the middle meatus of the nose. The examination of a large number of frontal sinuses in the moist and dry state discloses many points of interest. In the first place there is no space between the tables of the frontal bone before the seventh year. There may be a complete absence of these cavities even in extreme old age. I have bones in my possession showing a frontal sinus only on one side. The extent of the frontal sinuses varies widely, and unfortunately the external appearances of the skull give no indication of these variations. The frontal sinuses are seldom symmetrical, except in a general sense. Of the extent of these spaces there are specimens in the Museum of the Royal College of Surgeons of England, showing a separation of the inner and outer tables of the frontal bone almost to the coronal suture. The orbital plate of the frontal bone is frequently the site of a large cavity, communicating with, and forming part of, the frontal sinuses. The frontal sinus of one side may not communicate with the nose or its fellow of the opposite side, but may communicate with the anterior ethmoidal cells of the same side. The septum dividing the two sinuses is usually partly bony and partly fibrous, but is always well marked. It may be entirely bony or entirely fibrous. Its central position is constant. I have never found a frontal sinus not in communication, directly or indirectly, with the nose. The evolution of the frontal sinuses is not complete until the twenty-first year.

Hosted by Google

Development.—In the records of the Transactions of the Provincial Medical and Surgical Association for 1883, vol. i., appears a very able and highly suggestive article on "The Development of the Frontal Sinuses." by Dr. Milligan, of Edinburgh; also in his notes on "Majendie's Physiology" are some pertinent remarks in the same direction. Milligan shows that the functions of the two tables of the skull are quite different—that the inner table, being moulded closely to the fissures and convolutions of the brain, is mainly supporting and protective to that organ alone; next, that the brain arriving at its full state of maturity at seven years of age, the inner table ceases to grow or to expand after that date. Not so the outer table, which is an irregular envelope, at some places as thin as a wafer, at others thicker than all the rest of the cranium. If viewed from without we find that every particle of its surface is adapted to some purpose it has to answer in combination with the soft parts it is in contact with. Many prominences are levers for the muscles; others are scabrous surfaces for their insertions; others are condyles for joints; others organs of hearing; others organs of fixation; others of protection. And all this in direct reference to the organs of contact, but without the least relation that can be discovered to the encephalon. Hence we are forced to conclude that its projections solely originate under the influence and for the completion of functions that are external to the cranium. The evolution of the frontal sinuses does not take place till the seventh year, nor is it complete till the twenty-first year. At the seventh year the bones of the face are yet small and childish and the jaws are occupied by the first set of teeth. At this time the Wenzels inform us from many observations that the brain has arrived at its full magnitude. Up to this time the internal carotid artery was many times larger than the external, but immediately after full development of the brain has taken place a sensible diminution in its calibre occurs and a rapid and large increase is apparent in the external carotid and its branches. The bones of the face, the teeth, eyebrows, and outer table of the skull now grow rapidly, and, the internal table being at a standstill, large spaces occur between the tables of the skull; hence the frontal sinuses. In dealing with the diseases and surgery of the frontal sinuses one is struck with the fact that the patients do not apply for relief to the institutions most capable of affording relief. Seeing, indeed, that these are essentially cases for the general surgeon who at the same time has a special knowledge of the diseases of the nose, and primarily in no sense ophthalmic troubles, it is unfortunate that in most cases these patients apply for relief to the various ophthalmic institutions. The records of the special hospitals for diseases of the nose and throat are almost blanks; but, on the other hand, if anyone examines the reports from the various ophthalmic hospitals he will find many cases recorded of affections of these spaces. This is accounted for by the fact that accumulations of fluid, be it pus, serum, or mucus, or what not, in ninety-nine cases out of a hundred, bulge or perforate the roof of the orbit and protrude at its upper and inner angle under the upper eyelid, usually causing diplopia as a prominent, and often to the patient only, symptom. The records of these cases are not a few, and the names of ophthalmic surgeons are invariably associated with them. Hulke, Lawson, Soelberg Wells, Bell Taylor, and many others have each reported one or more cases.

The lining membrane of the frontal sinuses is but an extension of the lining membrane of the nasal cavity through the infundibulum. It differs widely in character from the nasal lining membrane. It is extremely thin, and in the healthy state pale in colour, and intimately adherent to the subjacent periosteum. From these differences in anatomical character it follows that the lining membrane of the frontal sinuses would probably not be subject to the same *rôle* or list of diseases that characterise the more vascular and complicated lining membrane of the nose proper. By far and away the most common affection of these spaces is catarrh, in one form or another, leading commonly to distension and abscess by the retention and accumulation of the products of inflammation. The pressure of the retained fluids bulges in some cases the bony casement at its weakest point, the roof of the orbit causing displacements and protrusion of the eye. Cases are not unknown where the contents have pressed backwards and necrosed the bone, and so entering the arachnoid cavity have set up a fatal meningitis or abscess of the brain. Again, the pus—although rarely—may bulge and perforate the bone in a forward direction. Cases, again, occur where the accumulation is intermittent, the pressure due to retention forcing the normal passage into the nose. These latter cases are not marked by a protrusion into the orbit, and being free from any gross external signs to assist the diagnosis are, as a rule, unrecognised. To this class of cases the term "latent empyema" of the frontal sinus is, I think, properly applied. The diagnosis and treatment of these two classes of cases is radically different. In the former we have to make a diagnosis and differentiate from distended lacrymal sac, dermoid cysts, cellulitis of orbit, exostoses, and new growths. In latent empyema of the frontal sinus the diagnosis to a large extent depends upon subjective symptoms alone. In the one class of cases the first and only symptom may be a displacement of the eyeball associated with diplopia, but unaccompanied with pain or uneasiness at the root of the nose. Latent empyema of the frontal sinus is not necessarily associated with any other affection in the throat or nose. The onset is usually undefined, and patients have merely perceived that from a certain date without well-marked cause they began to suffer from pain and uneasiness in the situation of the frontal sinuses (Professor Ogston). After a while headache at the root of the nose, varying in intensity but always present, is a main feature of these cases. A discharge of pus, not abundant but variable in quantity if looked for, may generally be made out. Pus may also be found at the anterior part of the roof of the cavity, but is small in amount and rarely visible. Pain or tenderness on pressure may or may not be present, but percussion with the fingers or a pleximeter generally elicits some uneasiness. The pain varies in some degrees, it is constantly present, but is seldom acute or unbearable. Bending forwards, stooping, or reading increases the trouble, and as a rule it is increased when in the recumbent position and after sleep. Dull, damp, and rainy weather increase the discomfort, but high altitudes and bright and dry atmospheres improve matters considerably. Many of these cases escape diagnosis, and are treated with bromides and iodide of potassium, shower baths, and the usual list of remedies for headaches without material benefit. I have the notes of several cases of latent empyema of one or both frontal sinuses where with symptoms such as related above the diagnosis has been made, and on the sinuses being trephined from the front the lining membrane has been found so granular as almost to constitute a polypoid state. In other cases many actual polypi have been found. These cases have without exception in my own hands done well, leaving on the forehead scarcely an indication of the site of the operation. In latent empyema of the frontal sinus to reach and effectually treat the disease by way of the infundibulum is, in my experience, practically out of the question. Resort must be had, then, to opening the sinuses in front at the root of the nose in the mid-line, or at the inner and upper angle of the orbit. A strong and fatal objection to this latter procedure being that the empyema may be one-sided, and it is impossible as yet to make sure on which side the disease is located. The procedure requisite to open the frontal sinus from the front is the following: The patient being anæsthetised, preferably with chloroform, and the interval between the eyebrows being divested of any hairs and made scrupulously clean, a note is to be made of the exact spot in the mid-line on a level with the upper margin of the orbits. This, for the purposes of the operation, may be termed the "pin spot," as it is the spot where the pin of the trephine is subsequently placed. An incision should be made exactly in the mid-line commencing at the root of the nose below the glabella and carried upwards for about two inches. In this incision everything is divided to the bone. There is no hæmorrhage as a rule. Next the pericranial covering is raised by an elevator and retracted to each side with blunt hooks or retractors. Bone to the extent of a five-shilling piece will now have been exposed. A trephine with a crown the size of a sixpenny-piece or less should now be so placed on the glabella that the pin of the trephine enters the bone at the "pin spot." The trephine is worked in the usual way with caution, examining with a fine probe the depth of the incision after every few twists. As it is important to remove the button of bone without lacerating or opening the lining of the sinus great care must be observed during the last few twists of the trephine. The trephine does its work first below and there is always some difficulty in removing the button, the bony septum or arch dividing the sinuses retaining it above. By careful manipulation with an

Hosted by Google

elevator the button of bone is detached, leaving the mucous lining of the sinus intact. This step is important for the following reasons. One or both sinuses may be healthy. The nature and character of the contents is obscured by admixture of blood. There may be no frontal sinus, and the cerebral cavity may be below what is supposed to be the lining membrane of the sinus. One or both sinuses, according to circumstances, is, or are, next to be opened with forceps and scissors and examined. Any secretion is to be removed. Any disease of the mucous membrane is to be treated by curetting or chloride of zinc, or both. Any polypi are to be removed, and the stumps treated with caustic, if requisite. Above all things, an opening must be established with the nasal cavity, and a drainage-tube inserted and maintained in position. Daily ablutions with antiseptic fluids will keep up a healthy action and assist a cure. The wound is to be accurately joined, the pericranium and pericranial aponeurosis, as well as the skin, being separately and carefully adjusted. The tube may protrude from the centre of the wound for the first few days for the purposes of irrigation, but subsequently may be shortened or dispensed with entirely. The result of this operation is usually immediately beneficial. The patients lose their troublesome symptoms and are permanently relieved. The wound healing by first intention there is no scar or disfigurement, and the line of the incision is scarcely perceptible. The method adopted by ophthalmic surgeons of treating the other and more common class of cases as illustrated by a protrusion and displacement of the eyeball is rarely satisfactory. Lawson, Hulke, and others have laid down the rules and steps of the operation for opening the frontal sinuses at the upper and inner angle of the orbit at the most prominent point of the swelling with great exactitude. I have adopted this procedure seldom with more than temporary benefit, and never with speedy relief or cure. In this procedure the protrusion in the orbit is attacked and opened at its most prominent point. The incision is made through the orbicularis muscle, suspensory ligament of the eyelid, and often close to the pulley of the superior oblique muscle and in proximity to the lacrymal sac. The opening speedily closes and granulations spring up, impeding the discharges and ultimately hampering the movements of the lids and leaving a nasty scar and much disfigurement of the parts. More than this, during the operation no clear or exact view is obtained of the interior of the sinus or lining membrane. In this operation it is most difficult to find the infundibulum or enlarge the same, if required, from the orbital opening. A drainage-tube in the upper eyelid is most annoying to the patient and most unsightly. Experience shows that these cases treated thus go on discharging for years and are not cured. I have long discarded opening the swelling in the orbit. I now always trephine in the front, a little to one side of the mid-line, and treat the case after the method of a latent empyema. Six weeks will usually suffice to cure these cases if operated on from the front. More rare affections of the frontral sinuses next to accumulation of fluids or pus are exostoses, polypi, and new growths. Exostoses are very rare and are usually of the hard description. There is one specimen in the Hunterian Museum, a large one, filling both sinuses and protruding into the nose and orbit. The museum at Cambridge contains another specimen, and a third is to be found at the museum of St. Bartholomew's Hospital. Mackenzie had two small specimens found, I believe, unexpectedly post mortem. Polypus of the frontal sinus of any size or in the form of pedunculated growths is rare, but when occurring is usually associated with the same disease in the nose. Mr. Hulke[1] reported several cases of polypus of the frontal sinus, only one case of which was unassociated with a similar state of things in the nose. These cases generally led to accumulation in the sinuses and were not primarily diagnosed as polypi. New growths are extremely rare, but sarcoma has been reported as presumably originating in these spaces. Of insects in the frontal sinus cases have been reported by Mackenzie and others. One interesting case of foreign body in the frontal sinus was under my own care—the only case of the kind, so far as I am aware, on record. During the exhibition of snuff a quantity was drawn into an unusually patent frontal sinus, and set up the most intense inflammation with great headache, high temperature, and delirium.

Harley-street, W.

[1] THE LANCET, March 14th, 1891.

OBSERVATIONS UPON RE-VACCINATION.

BY ROBERT J. CARTER, M.D. LOND., D.P.H. ENG.

DURING a recent small-pox epidemic I collected notes of 319 cases of re-vaccination. Calf lymph prepared with glycerine was used in every case, and the operation was performed indiscriminately on all persons who presented themselves, the ages varying from four to sixty years. Four insertions were made in the usual situation on the arm in every case, and only those arms which presented a vesicular stage on the eighth day after the operation were accounted successful. At the same time short notes as to the clinical condition of the patients were taken. The results obtained show very clearly how rapidly in early life the effects of primary vaccination wear out, the insusceptibility to re-vaccination being of a much more evanescent character than is generally believed. For the purpose of showing this clearly I have arranged the successful cases in two Tables. Table A comprises 148 children up to, and including fourteen years of age, all vaccinated in infancy; Table B comprises 171 adults over twenty-four years of age, vaccinated later in life than the fourteenth year.

TABLE A.

Number of years since last vaccination.

4	5	6	7	8	9	10	11
S. F.	S. F.	S. F	S. F.	S. F.	S. F.	S. F.	S. F.
3 —	6 —	7 —	6 —	15 1	14 —	19 —	20 —

12	13	14
S. F.	S. F.	S. F.
15 —	16 —	26 —

TABLE B.

Number of years since last vaccination.

1	2	3	4	5	6	7
S. F.	S. F.	S. F.	S. F.	S. F.	S. F.	S. F.
— 12	— 13	— 6	— 8	— 2	— 6	— 1
8	9	10	11	12	13	14
S. F.	S. F.	S. F.	S. F.	S. F.	S. F.	S. F.
1 4	1 2	2 2	1 —	1 2	2 8	— 3
15	16	17	18	19	20	Over 20
S. F.	S. F.	S. F.	S. F.	S. F.	S. F.	S. F.
2 1	— 2	— —	1 —	— 2	— —	82 4

Comparing these results somewhat in detail, it will be noted that of those under fourteen years of age vaccinated in infancy the earliest successful case is four years after the primary vaccination, whilst in Table B the earliest successful vaccination is after a lapse of eight years. In Table A the only three cases vaccinated at the fourth year were all successful; in Table B the earliest successful case occurs in the eighth year after previous vaccination. The proportion of failures to successes gradually diminishes in Table B. In Table A the solitary unsuccessful case is probably an accident. Practically at the tenth year re-vaccination of children vaccinated in infancy always results in a more or less typical vaccinia, whereas in adults it is not until about twenty years after a previous vaccination—and not always then—we can ensure any successful result. I feel that the paucity of numbers and possibilities of failures due to the vaccinator tend to depreciate these results, but when allowance has been made for such deficiencies I consider they still will bear the interpretation I have put upon them—viz., the greater rapidity with which the effects of vaccinia upon the organism wear out

Hosted by Google

in early life compared to more mature age. The explanation of this, I venture to suggest, is that up to puberty the tissues are in a much more active condition; tissue change is more rapid, and impressions on the organism more easily effaced than in adult life.

The Local Government Board do not allow public vaccinators to be paid for re-vaccinations upon children under ten years of age; but in the face of these results I would suggest that in small-pox epidemics every child in whose case four years have elapsed since the primary vaccination should be re-vaccinated. The condition of the arm on the eighth day after re-vaccination varies exceedingly. The areola appears much earlier than in primary vaccination. In 197 cases it was present on the second day. On the eighth day it varies from a circumferential blush around the vesicles to a uniform redness extending from the shoulder to the elbow, of a bright crimson colour, disappearing on pressure. I regard this condition as different to that in which we see œdema and redness extending down to the finger-tips. Some enlargement of the axillary glands can always be discovered if looked for. In 106 cases these glands were large, hard and tender, and in some instances exquisitely painful. In three cases the glands above the clavicle were also affected. Lymphangitis was present in nine cases, the lymphatic vessels being felt as hard, swollen, tender cords along the course of the axillary vessels. Induration and œdema of the arm were present in ninety-eight cases, and were of a curiously persistent character. They did not appear to be associated entirely with the glandular affection, but were apparently dependent upon the intensity of the local inflammation at the site of the vaccination.

Constitutional symptoms, except the temperature, are difficult to estimate, apart from the idiosyncrasy of the patient. Several complained of aching pain in the lumbar region, headache and nausea which, while not uncommon symptoms of a febrile condition, are the cardinal symptoms of the early stage of variola. Lassitude, giddiness, and loss of appetite were common among the male adults, whilst fainting and neurotic manifestations were noticed among the females. Post-vaccinal rashes were only seen in four instances. It was impossible to take the temperature of all the cases, but in those in which fever was noted the pyrexia appeared directly proportional to the amount of inflammatory action in the arm. It is commonly accepted that the amount of inflammatory action depends to some extent on the active use of the arm during the week following vaccination. In all my cases the occupation was noted, and it was found that the most severe cases occurred in women who had worn slings directly the vaccination showed signs of being successful. Its severity appears to me to depend entirely upon the general constitutional condition and the environment of the individual.

The treatment of severe cases was simple and apparently successful—free saline purgation, rest for the arm, the application of a lead and opium lotion, early and frequent removal of the scabs, and a boracic ointment dressing for the subjacent ulcers.

Acacia-road, N.W.

THE CONTINUOUS ADMINISTRATION OF NITROUS OXIDE GAS AND OXYGEN DURING MINOR SURGICAL OPERATIONS.

BY H. BELLAMY GARDNER, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT ANÆSTHETIST TO CHARING-CROSS HOSPITAL.

EIGHT years have elapsed since the possibility and distinct advantage of giving small percentages of oxygen with nitrous oxide gas to produce anæsthesia at ordinary atmospheric pressures were first pointed out in THE LANCET by Dr. Frederic Hewitt.[1] Though this method has now obtained a very wide and substantial footing in the dental profession, it can hardly be said that its remarkable value in prolonging the anæsthesia and rendering the patient flaccid and free from spasm for several minutes at a time has procured sufficient recognition among surgeons, who would have been expected to readily appreciate a mixture which leaves neither nausea nor mental disturbance after its inhalation, and, more important still, which subjects a patient to the least possible risk incurred by the exhibition of any known anæsthetic agent. The presence and concurrent inhalation of from 10 to 15 per cent. of oxygen with nitrous oxide gas are sufficient to maintain the due proportion of oxy-hæmoglobin in the arterial blood, and thereby to render an inhalation which formerly was cut short by the supervention of asphyxial symptoms capable of being sustained while many minor surgical operations are being effected. While the condition produced by the presence of oxygen is clinically free from asphyxial symptoms in those surgical procedures which are undertaken after removal of the face-piece, I have also found that a very tranquil anæsthesia may be obtained in those others which permit of its continuous application, even with quantities of oxygen rather larger than those usually administered in the first class of cases. To illustrate the kind of painful operation for which I think this method has proved to be appropriate the following cases are taken from my notebooks.

CASE 1.—A man, aged forty-seven years, with good chest expansion, stoutly built, and of rather florid colour, required the removal of four sebaceous cysts from the scalp. Before the administration he was seated in a comfortable armchair. The surgeon washed and prepared the skin around the cysts, and the face-piece was then applied. Commencing with a small percentage of oxygen (to allow for that already present in the lungs), the amount was gradually increased whilst the lid-reflex disappeared. Breathing continued deep and free as during sleep; the colour was good; no inconvenient movement occurred; and the operation—during which the cysts were excised and the incisions sewn up—proceeded for five and a half minutes. At its completion the patient awoke—one minute after removal of the face-piece—without any untoward sensations whatever.

CASE 2.—A girl, aged seventeen years, of average height and build but rather anæmic, suffering from a tuberculous abscess in the left side of the neck, was seated in an upright chair with a head-rest while the swelling was incised, thoroughly scraped, cleaned out, and then sutured with four separate stitches. During this operation, which lasted four and a half minutes, she was kept absolutely tranquil with a good, regular pulse under the influence of nitrous oxide gas and oxygen. The recovery was rapid and presented no after-effects of any kind.

CASE 3.—A man, aged thirty-five years, of average height but rather thin and pale, had two suppurating cysts on the scalp, one of which was very painful. He was seated in an easy-chair when the face-piece was applied. Again the percentages of oxygen with the gas were gradually increased until he was softly snoring as if under chloroform. The pupil remained of moderate size and the pulse and colour were very good whilst the incision, scraping, and dressing of the inflamed areas were completed. This operation also lasted four and a half minutes. He afterwards said it was very pleasant to inhale, that he felt quite well, and had not the slightest sensation or consciousness during the administration.

In the course of my work at Charing-cross Hospital I have lately administered nitrous oxide gas and oxygen during the excision of a varicocele lasting fourteen minutes. The patient, who was a male, aged twenty-two years, of a rather florid type, was inclined now and then to become a trifle dusky in colour, but this was owing to there not being quite sufficient oxygen at command; his absolute flaccidity and quietude during the time were, however, quite satisfactory to the operator. His breathing remained regular and the circulation was well maintained throughout. Recovery was complete in two minutes and he was not sick subsequently.

It has been my custom for the past two years to administer this anæsthetic in the aural department for the removal of post-nasal adenoid growths, and the advantages which may be claimed for its use are: (1) that it is not attended with danger to life; (2) that preparation for the operation is not absolutely necessary, though undoubtedly the *best* results are obtained after abstinence from food for three or four hours; (3) that hæmorrhage is unaffected by it; (4) that the jactitation and cyanosis produced by pure nitrous oxide gas are absent; (5) that any posture desired by the operator may be safely assumed; (6) that when the face-piece is removed the available anæsthesia is about fifteen seconds longer than that

[1] THE LANCET, April 27th, 1889, p. 832.

Hosted by Google

yielded by gas alone; and (7) that unpleasant after-effects of any kind are of very rare occurrence. After an experience of several hundreds of cases I ought to state that during this operation some of the patients will move a little and in some there will be a little phonation; but, on questioning them it will be found that they felt nothing of the operation and would quite willingly take the anæsthetic again. This result is not often attainable with gas alone, for children yield a very short anæsthesia under its influence and may be very blue and rigid, whilst if oxygen be present there will be muscular relaxation with good normal colour.

For the removal of enlarged tonsils the mixture is a distinct improvement upon gas alone, because there is less venous turgescence and therefore less swelling of the tonsils and tongue, with a corresponding immunity from obstructed breathing during unconsciousness. Incision of the tympanum, removal of aural and nasal polypi, and other procedures of a like nature have also been successfully accomplished under its anæsthetic influence.

I believe that for the painless movement of stiff joints and the stretching of adhesions in their vicinity it forms by far the most suitable agent at our disposal, because muscular flaccidity is quickly produced and the patient will not object to a second inhalation of these tasteless gases if the operation has after an interval to be repeated.

In sensitive subjects the passage of a catheter is often a matter of apprehension and pain; those who would otherwise resist the surgeon's manipulations can be kept quietly unconscious by inhaling the mixture until this procedure is accomplished and fear of suffering is at an end. I hold that it is an anæsthetist's aim and ideal to render his patient insensitive to pain with as little damage to the physiological processes of his system as possible, and for these or similar operations I find this method a great improvement upon gas alone, while the danger of chloroform and the sickness resulting from the use of ether are entirely avoided by its employment.

Welbeck-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CLINICAL NOTE ON THE PROPERTIES OF ACETANILID.

BY EDWARD F. GRÜN, M.R.C.S. ENG., L.R.C.P. LOND.

IN THE LANCET of June 27th, 1891, you were kind enough to insert an article written by me on the treatment of what I designated "Specific Bronchitis." In that article I adverted to the germicidal properties of what at the time was a comparatively unknown drug, acetanilid, giving bacteriological proof of the very high comparative value in arresting growth of all forms of micro-organism in nutrient media, and urging medical men to give the drug a trial. Since that date—now nearly six years—I have taken every opportunity afforded me by private practice to test the value of this compound as a dressing for wounds, and the result of my experience is that for convenience, reliability, and general utility there is no antiseptic drug to equal it. This question is so easy of proof (which is not always the case with drugs recommended for internal use) that I feel the preparation has only to be thoroughly tested under fair conditions to become universally accepted as the dressing for wounds *par excellence*. During the past six years among a number of cases which have come under my care the following will serve to illustrate the valuable healing powers of this compound of aniline. There is no necessity to quote the names of the cases, but many were seen by members of the profession beside myself, and I can, if necessary, give the full details. It is sufficient to say that every one healed without the formation of pus and the majority by first intention, although the operations described were often performed under conditions which rendered antiseptic precautions absolutely impossible.

CASE 1.—July 14th, 1895: A compound fracture of the metatarsal bone, caused by the wheel of a waggon loaded with two tons of coal passing over the foot of a man, was complicated with severe laceration of the skin. The patient was able to resume work in about twelve weeks from the date of the accident.

CASE 2.—Aug. 18th, 1895: After amputation of the forearm of a woman union by first intention resulted, and the dressings were removed at the end of a fortnight.

CASE 3.—Sept. 30th, 1894: A man was operated upon for strangulated hernia. The operation was performed in great haste in a cowshed, the sac being opened and Gimbernat's ligament divided. The patient was removed to the infirmary at Alton on the same day, and was discharged cured at the end of seven days. The wound healed by first intention.

CASE 4.—1893: This was a case of removal of the breast for suppurating cancer. The breast had been injected with methyl-violet, according to Professor Moestig's method, which caused suppuration of the cancer. The breast was subsequently removed. The wounds were entirely healed at the end of ten days.

CASE 5.—In this case the operation of amputation of the leg was performed in the tap-room of a public-house. The patient was removed to the hospital, and he subsequently made a very good recovery.

The foregoing are the most serious cases in which I have made use of acetanilid as a dressing for wounds. In addition to these I have made use of the remedy in innumerable cases of minor surgery, such as removing fingers or toes, burns, lacerations, &c. I was induced to try the drug in 1891 on purely theoretical grounds, and am happy to say that in actual practice the beneficial results far exceeded my anticipations. As many of your readers may not be acquainted with the physical properties of this compound I may say that it is a white, crystalline powder, quite tasteless, inodorous, and almost innocuous when taken internally up to quantities of from five or ten grains. It may be mentioned that occasionally it causes a bluish tinging of the skin and some blueness of the lips and finger-nails. The urine occasionally is tinged with blue. The bluish discolouration I believe to be due to some impurity which was formerly present in the commercially prepared compound, for latterly I have failed to notice any of this colouring in patients under the treatment. The drug is applied as a dry powder, when it appears to cause a dry, healthy scab on lesions of continuity, and a gluing together of the edges of incised wounds. Recently I have been using this remedy for treatment of ulcerated legs in old people, and find that in the majority of the cases a clean, dry surface is formed in a few days and healing rapidly promoted without the necessity of bandaging or strapping.

Southwick, near Brighton.

"FUNCTIONAL ACTIVITY OF MAMMARY GLAND IN AN INFANT."

BY F. S. D. HOGG, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON, WEST LONDON HOSPITAL.

MR. HAWTHORNE'S communication on the above subject in THE LANCET of May 29th is of interest as relating to a somewhat unusual occurrence in the infant and one which is not referred to by many writers on infantile complaints. I came across such a case a few days ago. I was asked to see a female child, one week old, on account of her having vomited a small quantity of blood and, as the nurse believed, having passed some blood by the vagina. On examining the child I could find nothing amiss with her excepting that the breasts were considerably enlarged, not painful, and a milky fluid could be expressed on slight pressure. I directed that this milky fluid should be expressed occasionally, and have heard nothing further of any trouble with the child. The mother of this child and the nurse who was with her at all her confinements stated that both her former children (a boy and a girl) secreted a milky fluid in the same manner, and the mother further states that as infants she and her brothers and sisters were similarly affected. I have only seen one other case, in a child, a female, now eight years old, whose breasts do not now at all differ from those of other children of her age; but on the hearsay evidence of several mothers and nurses I think that this condition must be more frequent

Hosted by Google

than the absence of all mention of the subject in most of our text-books might lead one to suppose.

Tillingham.

A MARKED HISTORY OF SYPHILIS.

BY E. CECIL WILLIAMS, M.B. CANTAB.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL.

THE following history may prove of interest to the readers of THE LANCET on account of its completeness and the remarkable fertility of the woman.

The patient, aged forty-two years, married twenty years, had been pregnant twenty-one times. She was fragile and debilitated, had had no serious illness, but shortly after marriage she had a primary sore, followed by sore-throat and a well-marked rash over the body, for which she was under treatment for ten months. She says that her husband was suffering from syphilis at the time of her marriage. The eldest child was born ten months after marriage, and died at seven weeks. The child had well-marked signs of congenital syphilis. The second pregnancy resulted in a miscarriage at six months; the third in the birth of an eight-months' child, dead; the fourth in the birth of an eight-months' child, dead; the fifth in the birth of a child at full time, who lived two years and seven months, and was rickety; the sixth in a child born dead at six months; the seventh in the birth of a child who is still living and fairly healthy (now aged fifteen years, but has rather a characteristic expression); the eighth in the birth of twins at full time, both dead; the ninth in a child born dead at eight months; the tenth in the birth of a child at full time, who died at the age of nine months (had snuffles and rash on buttocks); the eleventh in the birth of a child at full time, who is alive and fairly healthy; the twelfth in a miscarriage at four months; the thirteenth in a miscarriage at three months; the fourteenth in the birth of a child at full time, who is living; the fifteenth in the birth of a child at full time, who died aged seven weeks; the sixteenth in a miscarriage at three months; the seventeenth in a birth at eight months, the child dying at the age of seven weeks; the eighteenth in a miscarriage at four months; the nineteenth in the birth of a child at full time, who is three years of age and healthy; the twentieth in the birth of a full-time child, who is two years of age, but rickety; and the twenty-first in the birth of a child at full time (now aged six months), who is markedly syphilised and has snuffles, excoriations on the buttocks, and is wasting. The mother presents no symptoms of tertiary syphilis. She says that since the secondary symptoms, twenty-one years ago, she has had no symptom of the disease, but she has suffered from leucorrhœa and bearing-down pains. It certainly appears as though she had been rendered immune to the disease. I have seen two of the children; they have the facial expression of congenital syphilis, but appear to be fairly well. From what I could gather from the mother those that died were markedly syphilitic.

Bristol.

LONGEVITY.—A correspondent has forwarded to us a paragraph which has recently come under his notice, giving the following instances of longevity. It was taken from the *Saltburn-by the-Sea and Guisboro' Herald* of Sept. 2nd, 1887: "There were interred in the Skelton Churchyard, on Sunday last, the remains of an old resident, Mary Husband, aged 101. In the same churchyard is to be found a tombstone recording the death of James Moon, aged 106; his wife, 84; and his sister, 101."

THE annual meeting of the Association of Registered Medical Women was held in the library of the Association (New Hospital for Women) on June 1st, at 8 P.M. There were present Mrs. Garrett Anderson, M.D. Paris, retiring President, in the chair, and twenty-four members. The proceedings were of a business character; the managing committee and sub-committees for the ensuing year were elected and the constitution of the association was reconsidered. Miss Cock, M.D. Brux., was elected president for the year in succession to Mrs. Garrett Anderson, and Mrs. Stanley Boyd, M.D. Brux., was elected vice-president.

ST. THOMAS'S HOSPITAL.

A CASE OF STRANGULATED FEMORAL HERNIA; GANGRENE OF BOWEL; PRIMARY RESECTION; RECOVERY.

(Under the care of Mr. H. BETHAM ROBINSON.)

THE best method of treatment to be employed in cases of gangrene of the bowel resulting from strangulated hernia is by no means settled. Two plans are open to the surgeon; he may at once resect the gangrenous gut and suture the divided intestine, or he may content himself with making an artificial anus and postpone to a future occasion the operation for restoring the continuity of the bowel. Primary resection of the intestine is by no means new; it was done in 1794 by Nayler, of Gloucester, and in two cases Sir Astley Cooper performed it, advising it in the following words:[1] "When the whole cylinder of the intestine is mortified it is necessary to proceed very differently. Then the mortified part of the intestine should be cut away and the ends are to be brought in contact and confined by means of four sutures," though Sir Astley Cooper saw fit later to modify his opinion. The formation of an artificial anus, though easily and rapidly carried out, necessitates a second operation later, and this naturally greatly increases the risk. If reliance could be placed on statistics the question would be at once settled, for Kendal Franks[2] gives the mortality after primary suture in 220 cases as only 48 per cent., while the death-rate of the cases in which an artificial anus was made was 80 per cent., and of the secondary resections 38 per cent. Zeidler[3] gives the following mortality in cases of gangrene of the bowel in herniæ in St. Petersburg:—Of 289 cases of primary resection 49 per cent. died, and of 287 cases in which an artificial anus was formed 74 per cent. died. These results are even more striking when we compare them with the statistics collected by Berry[4] of all cases of strangulated hernia in ten years in the hospitals of St. Bartholomew's, Guy's, and St Thomas's; of the 946 cases the mortality was 44 per cent, or only a little less than the mortality after primary resection. There are, however, many fallacies in these statistics of the treatment of gangrenous bowel. In the first place, many of the unsuccessful cases of primary resection undoubtedly never find their way into print; and secondly, primary resection is generally only employed in cases in fair general condition, and in all moribund cases the surgeon contents himself with making an artificial anus. Another fallacy is due to the difficulty of being certain in many cases that the bowel is really beyond recovery, and it is by no means improbable that the list of successful cases includes some in which an unnecessary resection has been made; but even when all these sources of error have been taken into account most surgeons will agree that primary resection is the preferable operation in suitable cases. Indeed, the general condition of the patient at the time of the operation is the only trustworthy criterion of the course to be adopted. Should the strangulation have been of long standing, and the patient be utterly collapsed, it is unwise to waste time in doing a resection, and an artificial anus holds out the only hope of a successful issue; but should the general condition of the patient be fair and the pulse good a primary resection offers the best chance of a cure. There is an objection to an artificial anus to which often sufficient importance is not attached; if the opening into the bowel is at a point higher than the lower part of the jejunum the lack of absorption of the products of digestion may be so great that the patient may die from exhaustion, even though taking an abundance

of food.[6] Sir William MacCormac in his Bradshaw Lecture,[6] after advocating primary resection in suitable cases, recommended that the resection should be performed at the site of the hernia in the inguinal variety, but through an abdominal section in the femoral form. Primary resection has many advocates, as Chaput,[7] C. B. Lockwood,[8] Kendal Franks,[9] F. T. Paul,[10] and Heydenreich.[11] Recently some surgeons have advised the formation of a temporary artificial anus, followed after a very short interval by a resection; the interval may be from five days to three weeks.[12] This is an important modification, which will, without doubt, be of value in cases too profoundly collapsed for primary resection.

A widow, aged sixty-two years, was admitted into St. Thomas's Hospital on Oct. 3rd, 1896, suffering from a strangulated femoral hernia on the right side. She had noticed a swelling in the groin for about two years which had gradually become larger, but without causing any symptoms. For four days before admission this had been getting harder and uncomfortable, and there had been absolute constipation; vomiting had been frequent, but only bile-tinged. On admission to hospital the hernia was dense and hard, without any impulse, the skin over it was rather reddened, and there was considerable tenderness. At 10.30 P.M. the operation was performed. The incision was the usual vertical one, and on opening the sac blood-stained fluid with a faint fœtid odour escaped. The contents were omentum and gut. The omentum was matted and considerably ecchymosed; the gut, which was hidden under the omentum, was seen to be small intestine and very dark. The constriction at the neck was extremely tight, so that the hernia knife was introduced with difficulty. After releasing the structures and pulling the gut down it was seen that the dark gut was sodden and without polish, and had been so tightly gripped as to leave nothing more than peritoneum at the neck. As the woman's condition was extremely good it was decided to resect immediately. Assisted by Mr. Abbott, the resident assistant surgeon, the matted omentum was first removed and the loop of gut was then drawn down. As the damaged bowel was four inches in length five inches of bowel were removed with the corresponding wedge of mesentery. Before doing this Makins's clamps had been put on the bowel above and below. After the section the ends of the bowel were carefully cleansed and disinfected. Bleeding from the mesentery was free and particularly from the upper angle; so much was it so, and owing to some retraction under Poupart's ligament, that the latter structure was divided across, throwing the lower part of the abdomen and hernial sac into one. This proved a great gain, for not only could the bleeding mesentery be easily dealt with and its vessels secured, but afterwards it enabled the sutured bowel to be replaced with care and not subjected to the squeezing which is unavoidable through the slightly enlarged femoral ring. The assistance of any mechanical aid to suturing was dispensed with. Beginning from the mesenteric border the mucous membrane was brought together by continuous silk sutures, taking great care to lessen the lumen as little as possible. Lembert's sutures of fine silk were next inserted in a single row, the mesenteric border being securely covered in. The edges of the mesentery were brought together with a continuous silk suture, and the re-united bowel was placed in the lower abdomen over the femoral ring. The hernial sac was removed, the peritoneum of the lower abdominal wall was sutured, and the soft parts were brought together with silkworm gut and horsehair stitches. No drainage was used and the wound was dressed with cyanide gauze. Suturing the bowel took thirty-five minutes, and the patient's condition at the end of the operation was very satisfactory. Her progress was good and for the first few days without anything to comment on. Her temperature varied between 99·4° and 100·6° F. Nutrient enemata were given and the mouth was kept moist. On the evening of the 7th (the fourth day) she passed flatus freely and the enemata were returned. On the 8th she was not quite so well owing to a feeling of discomfort in the abdomen. There was a little fulness and she had an inclination to vomit. The tongue was moist and the temperature only 99·4°. A turpentine enema was given with a good result, a feeling of relief ensuing. The bowels were opened a little naturally in the evening. On the 9th, although she felt much better generally, she had passed a restless night, with some pain and distension. On exploring the wound there were found to be present some swelling and fluctuation at the lower part. Two stitches were removed and about three ounces of offensive, fæcal-smelling, dirty pus were evacuated. As this appeared to occupy the space of the original hernia a counter opening was made and a drainage-tube was introduced and the cavity washed out with boracic lotion. From this time she rapidly recovered. There was no discharge of fæces from the wound at all. The bowels were opened naturally again on the 12th and from then generally daily. The drainage-tube was taken out on the 13th and the wound soon healed. She was up on the couch on the twenty-first day after the operation, although she was rather weak and low, which was not surprising considering her age. She soon left the hospital and gradually recovered strength without any subsequent symptoms. As lately as the middle of April she was looking strong and well without any complaint. There was bulging over the seat of the operation, and for this an ingenious truss has been applied causing pressure on both lower abdominal and femoral regions.

Remarks by Mr. BETHAM ROBINSON.—In the first place, here is another case which demonstrates the feasibility of immediate resection of gangrenous intestine and its great gain to the patient if successful. This method of treatment, still on its trial so to speak, can only be judged by the result of cases collectively, although isolated cases may show successes. Undoubtedly many, because unsuccessful, get buried in oblivion, whereas, if recorded, they might assist in arriving at a positive conclusion. That it has its place there can be no doubt, and among the failures many factors have to be considered. Secondly, it will be noticed that simple suturing was adopted—a method probably, if done with fair speed, superior to all mechanical aids so far introduced. Lastly, the age of the patient shows that this need prove no barrier to success.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Musical Mitral Murmurs in Connexion with Aortic Stenosis.

A MEETING of this society was held on June 8th, the President, Dr. HOWSHIP DICKINSON, being in the chair. Various alterations in the by-laws proposed by the council were adopted, with trifling modifications. The most important was one diminishing the distance from the society's house within which Fellows were regarded as "resident Fellows," with the higher rate of subscription, from fifteen miles to seven miles. The congratulatory address to Her Majesty as patron of the society, drawn up by the council in accordance with the resolution passed at the previous meeting, was approved by the Fellows and signed by the President.

The PRESIDENT read a paper on the Occurrence of Musical Mitral Murmurs in Connexion with Aortic Stenosis. Four cases were related in which a systolic musical murmur, thought to be produced by mitral regurgitation, was associated with obstruction of the aortic exit. In one the mitral valve was practically sound; in the others the mitral valve was diseased as well as the aortic. Case 1 was that of a boy who had, together with much evidence of intra-ventricular tension, an intense apex systolic murmur which had a musical tone. After death the aortic orifice was found to be almost completely closed by recent vegetations; the mitral valve was practically natural. The mitral murmur, as it was thought to be, was the only murmur heard. It was attributed to the over-distension of the ventricle due to the obstruction of its aortic exit, and to consequent leakage of the mitral valve under the abnormal pressure to which it was subjected. Case 2 was that of a man who, after having been for some time under treatment with the ordinary signs and symptoms of disease of the aortic valve, developed a murmur indicative of mitral regurgitation which was attended with a definite squeak like that of a mouse. After death the

Hosted by Google

heart was found to be greatly hypertrophied, especially as to the left ventricle. The pericardial cavity was obliterated by old adhesions. The aortic orifice was obstructed by fibroid thickening, the mitral orifice being crescentic and contracted. The sound was presumably imparted to the murmur by the intra-ventricular tension occasioned by the ventricular hypertrophy and the state of the aortic exit. Case 3 was that of an old man who displayed shortly after admission, and shortly before his death, a systolic whistle in the mitral area. The left ventricle was found to be hypertrophied, the aortic valves calcified, and the opening contracted; the mitral valve was thickened, but the orifice was not dilated. Case 4 was that of a man, fifty-four years of age, who had at the apex a distinct systolic squeak like the high note of a fiddle. The heart was found to be hypertrophied. The aortic orifice was almost closed, partly by old rigid thickening and partly by recent soft vegetations. The edges of the mitral valve were slightly thickened, as also were those of the tricuspid. The musical murmur was attributed, as in the other cases, to the occurrence of mitral regurgitation in small volume and at high pressure, the high pressure being due to the ventricular hypertrophy and the aortic obstruction. The cases recorded were held to indicate that in aortic obstruction, together with hypertrophy of the left ventricle, a peculiar tone may be imparted to mitral regurgitation, probably in consequence of the force under which it is produced.

Dr. NORMAN MOORE thought that the President had done well in drawing attention to these cases, in which the nature of the lesion had been verified by post-mortem observations. It was too often the custom to speak as if everything were known about murmurs and their production. But there were many gaps in knowledge, particularly as regards post-mortem verification. Dr. Dickinson's explanation of the condition he described was ingenious and probable, but he still felt in some doubt as to whether it was the only possible explanation. He wished particularly to know what was the character of the murmur as heard at the patient's back. Following the teaching of the late Dr. Andrew, he had been led to assume that if a systolic apical murmur was lost in passing out into the axilla, and was inaudible at the angle of the scapula, it was probably of aortic origin. Now that attention had been drawn to these cases it would be most important for future observers to go carefully into the character of the pulse, and possibly the sphygmograph might give evidence as to whether there was mitral regurgitation. Dr. Moore remarked that it was often possible to obtain information as to the origin of a systolic murmur which was audible at the base as well as at the apex by listening at the right supra-scapular fossa and at the angle of the right scapula. If the murmur were heard loudly above, but faded away on passing downwards, and was inaudible at the angle of the scapula, the murmur was probably due to aortic stenosis only; but if the murmur became clearer at the angle of the scapula there was probably mitral regurgitation associated with aortic stenosis.

Dr. DE HAVILLAND HALL said that he had met with puzzling cases which he now thought might have been of this nature, but he had had no opportunity of making pathological observations. He asked Dr. Dickinson if there were any thrill in the cases.

Mr. F. J. GANT remarked on the unfavourable influence which such a condition of the heart would have on the prognosis if a patient were attacked with pneumonia.

The PRESIDENT, in reply, said that in some of the cases there were ordinary mitral murmurs present as well as the squeak, and they were conducted into the axilla in the ordinary way. In one case the squeak was heard in the axilla, but he could not say if it was conducted to the back. In only one of these cases was the squeak associated with mitral stenosis.

OBSTETRICAL SOCIETY OF LONDON.

Parturition during Paraplegia.

A MEETING of this society was held on June 2nd, Dr. C. J. CULLINGWORTH, President, being in the chair.

Dr. AMAND ROUTH read a paper on Parturition during Paraplegia, with cases. The patient was a multipara, with complete paraplegia below the level of the sixth dorsal vertebra, who was admitted into a surgical ward of Charing-cross Hospital under his colleague, Mr. Astley Bloxam, half an hour after the accident which caused the paralysis. She was then nearly seven months pregnant. For eight days uterine intermittent contractions were absent, when they became gradually more and more perceptible. After two months the patient was transferred to a special ward, and labour came on 261 days after the last menstruation without the patient feeling any pain. The first stage lasted ten hours, and the second two and a quarter hours. The placenta followed, aided by a slight "expression," in five minutes. The patient's only sensation during a "pain" was a "tight feeling" at the epigastrium, giving her an inclination to hold her breath, but this tightness was in no sense painful. As the head was passing the vulva the patient cried out, but this also seemed a reflex act and was unaccompanied with sensation of pain. The "pains" were not as well defined as in a normal case, the intermissions being often absent, as judged by the vaginal touch and the hand on the uterus. In fact, the "pains" rather remitted than intermitted. Retraction was not good for some hours, but there was no undue hæmorrhage. Uterine involution and lactation were quite normal. Death occurred six months later, and full details of the pelvic organs, the fractured spine, and the cord were given. The following views seem to be fairly established:—1. The act of parturition is partly automatic and partly reflex, these actions corresponding in the main to the first and second stages of labour respectively. 2. Direct communication with the brain is not essential to coördinate uterine action though the brain seems to have a controlling influence upon the "pains," helping to make them regular with well-defined intermissions. 3. Direct communication between the uterus and the lumbar enlargement of the cord, through the medium of the sympathetic ganglia between the first and third lumbar, is probably essential to the regular and coördinate contraction and retraction of the uterus, as occurs in normal parturition. 4. It seems also probable that the uterus is able automatically to expel its contents as far as the relaxed part of the genital canal even when deprived absolutely of spinal influence, spinal reflexes being then necessarily absent. 5. Lactation is not solely due to nervous influence, but partly to chemical changes in the blood.

Dr. MOTT remarked that he had examined sections of the spinal cord at the seat of the lesion, and had found that the crush had completely destroyed the nervous structure at the seat of the injury; but that apparently many cells in the anterior horn of the lumbar enlargement were fairly normal in appearance. Inasmuch as these were still in connexion with the uterus, this case did not prove, like the dog of Goltz, the independence of action of the uterus. He (Dr. Mott) had seen demonstrated at the International Congress at Berne the control of the sphincters in this animal, deprived previously of a great part of its spinal cord. The experiment proved that in the dog the uterus could contract effectually without cerebro-spinal influence, and that the sphincters could maintain their tonus—facts which upset all previous notions. It must be remembered, however, that the sympathetic chain and the posterior spinal ganglia remained. These are connected and probably formed the reflex arc which maintained the tonus in the sphincters. He ventured to suggest that the physiological stimulus for the blood of the onset of labour might be a bio-chemical condition of the fœtus at full term—e.g., an increase of carbon dioxide. That profound bio-chemical changes take place during pregnancy is highly probable; the enlargement of the mammary glands in this case after interruption of the spinal connexion between these structures and the uterus suggests this, and the fact that the mammary glands enlarge after all the nerves have been divided, both cerebro-spinal and sympathetic, proves that an altered condition of the blood can be the only means of bringing about disassociated functional activity in two remote structures.

After remarks by Dr. GILES, Dr. MCCANN, Dr. PEMBREY, Dr. HEYWOOD SMITH, Dr. HANDFIELD-JONES, Dr. JOHN PHILLIPS, Dr. BERTRAM ABRAHAMS, and the PRESIDENT, Dr. AMAND ROUTH replied. He agreed with Dr. Mott that the crux of the whole question was the difficulty in determining the cause of the onset of the labour at term. The cause was probably a bio-chemical one, and Dr. Mott's suggestion that this resulted from the accumulation of carbonic acid in the placental circulation was not likely to be rejected, for it was known that asphyxia produced uterine contraction and caused abortion if pregnancy existed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL MEETING of this society was held on June 4th, Mr. W. BRUCE CLARKE, President, being in the chair.

Dr. HENRY SUTHERLAND showed (1) a case of Epilepsy, the disease having commenced after a miscarriage at the fifth month; and (2) a girl, aged nine years, with congenital absence of the iris.

Mr. MCADAM ECCLES showed (1) a woman, aged forty-eight years, with Symmetrical Nodules of a Fibrous Nature on the posterior aspects of both ulnæ; she was affected with chronic rheumatoid arthritis; and (2) a man, aged seventy-five years, with a Rodent Ulcer of the Left Axilla. There was extensive superficial ulceration, with rolled edges, serosanious discharge, and slight induration. A microscopic section of the ulcer showed the usual appearance of rodent ulcer.

Dr. H. P. POTTER showed a man, aged fifty-nine years, with Scurvy due to privation. He had extravasations on the dorsum of each foot, in the calf of one leg, ecchymosis and purpura of the legs and arms, spongy and bleeding gums, with marked fœtor of the breath. Under a liberal diet, including potatoes, he was recovering.

Mr. L. A. BIDWELL showed (1) a woman, aged fifty-one years, with a Swelling connected with the Left Wrist and another on the outer side of the Right Elbow; they were probably of a tuberculous nature; (2) a man, aged thirty-four years, with a Primary Sore affecting the Right Cheek; and (3) a girl, aged seventeen years, who had had a Swelling just above the Hyoid Bone for ten months. This swelling had gradually increased to the size of a hazel nut.

Dr. BURRELL showed two cases of Mucoderma.

Dr. SEYMOUR TAYLOR showed a man, aged fifty years, who had had an Injury to his Head twelve weeks ago, when he was admitted to hospital in a comatose condition, with hæmorrhage from the right ear. He now has facial palsy, loss of taste in the right side of the tongue, and paresis of the right side of the soft palate; there was no deafness. The diagnosis was fracture of the petrous bone or hæmorrhage into the aqueduct of Fallopius.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on June 2nd, the President, Dr. ARGYLL ROBERTSON, being in the chair.

Mr. CATHCART showed a woman on whom he had successfully operated for Perforation of a Gastric Ulcer. He had seen the case seven hours after the onset of the symptoms and agreed with the patient's medical attendant that they were due to the condition indicated. At the operation it was found that the peritoneum generally was not affected. The perforation was found on the posterior wall near the lesser curvature. It was closed by folding in the edges and stitching the opposed surfaces together. He washed out the lesser peritoneal sac. The patient made an excellent recovery and was in better health than she had experienced for years.

Dr. STEWART STIRLING showed a child with Psoriasis in whom the distribution was unusual.

Dr. NORMAN WALKER showed a girl with Scleroderma of the Upper Arm, which had improved under the internal administration of thyroid extract combined with baths and massage.

Mr. MILES showed a specimen of Hydrocele of the Cord obtained as the testicle had to be removed for strumous disease. He also showed the bones from a case of Middle-ear Disease in which death was due to septic meningitis, notwithstanding free opening and other measures. The case clinically presented several of the characters of cerebral abscess.

Dr. ALEXANDER BRUCE made a communication on the Endogenous Fibres of the Lumbo-sacral Region of the Cord. These fibres occupy a small area on the posterior aspect of the cord at the side of the posterior fissure, and another area anterior to the postero-median column. These two areas were unaffected in locomotor ataxy, but were degenerated below the seat of lesion when the cord was destroyed transversely. He believed that the fibres in these tracts contained fibres derived from the posterior horns and united different levels of the cord. He held that the fibres had a downward course in the cord. The communication was illustrated by an admirable lantern demonstration and by sections shown under microscopes.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Distension of the Bladder with Air in Supra-pubic Cystotomy.—Pyloroplasty.—Fracture of the Metacarpal Bone of the Thumb.

A MEETING of this section was held on May 14th, Mr. WILLIAM THOMSON, President, being in the chair.

Mr. JOHN LENTAIGNE exhibited an apparatus for distending the bladder with air in the operation of supra-pubic cystotomy. It consisted of an indiarubber air-pump with reservoir of the same material, similar to that used with the ordinary hand spray. This was attached by means of a rubber tube to a silver catheter, which was introduced into the bladder. In using the apparatus the reservoir was first distended with air, which was then allowed to gradually distend the bladder, and the operation was then performed. If it became necessary to force the bladder forward in the wound pressure was made on the reservoir outside. Mr. Lentaigne had used this apparatus in a recent case, in which he had closed the bladder wound with catgut sutures, and the entire wound had healed by first intention.

Mr. LENTAIGNE also exhibited a patient on whom he had performed the operation of Pyloroplasty on Feb. 26th last for fibrous stricture of the pylorus with great dilatation of the stomach. The healing of the wound had been uneventful, and the patient, who was now apparently in perfect health, had gained over 2st. in weight.—Mr. MYLES said that if the operation of pyloroplasty took two hours in the hands of a skilful operator it compared very unfavourably with the operation of gastro-duodenostomy, which could be done in about twenty-five minutes. The results of the latter operation were also very favourable.

Professor E. H. BENNETT gave some further particulars in relation to the Fracture of the Base of the Metacarpal Bone of the Thumb in addition to those which he published in 1881 and in 1886. Continued observation has fully established this injury as the commonest metacarpal fracture. Photographs taken with the x rays confirm the view he had published as to the path of the fracture passing obliquely through the base without implication of the dorsal surface of the bone.—Mr. SWAN said that many surgeons had considered the injury to be a dislocation; it was not until he read Professor Bennett's communication in the *Dublin Quarterly Journal* of 1881 that he understood the nature of the injury.—Sir WILLIAM STOKES said that they owed the description of the injury to Professor Bennett, who had received very full recognition by eminent writers, not only at home, but in France and Germany, for having given the best description of the injury.

Reviews and Notices of Books.

A Short Practice of Midwifery, embodying the Treatment adopted in the Rotunda Hospital, Dublin. By HENRY JELLETT, B.A., M.D., B.Ch., B.A.O. Dublin University, L.R.C.P. Irel., L.M., Assistant Master, Rotunda Hospital. With a Preface by W. J. SMYLY, M.D., F.R.C.P. Irel., late Master of the Rotunda Hospital. With 45 Illustrations and an Appendix containing the Statistics of the Hospital for the last Seven Years. London: J. & A. Churchill. 1897. Price 6*s*.

DR. JELLETT has written this little book partly at the request of several of his pupils, and partly as an exposition of the principles that govern the practice at the Rotunda Hospital. There is an interesting introductory preface by Dr. Smyly, who indicates some of the main points in which that practice differs from what is generally taught elsewhere, and he expresses his responsibility for them.

Hosted by Google

Foremost among these may be mentioned plugging the vagina in cases of accidental hæmorrhage. Formerly, Dr. Smyly tells us, his custom at the Rotunda in all serious cases of accidental hæmorrhage was to rupture the membranes. The results under this treatment were not at all favourable. Latterly, therefore, he has altered his practice, and now in all cases of external accidental hæmorrhage, when the pains are absent or slight and the membranes are intact, he plugs the vagina tightly, and under this form of treatment the results have shown a great improvement.

There is a very excellent chapter on the subject of Antiseptics in Midwifery. The bacteriological condition of the vulva, vagina, and cervix is carefully described, as well as the means provided by nature when labour is normal and free from interference to protect the mother from any evil consequences. It is recommended that the external genitals and skin round should be washed thoroughly with soap and water. If any intra-uterine operation is about to be performed the vagina is disinfected as well. This is done by first douching with creolin solution (half an ounce to a gallon), then scrubbing its walls with a clean piece of soap and the fingers, and then douching again. Dr. Jellett objects to the use of corrosive sublimate in vaginal douching, as, apart from the possibility of poisonous effects, it causes roughening and brittleness of the vaginal mucous membrane, making it more likely to crack, and so facilitating the introduction of septic matter. The advice given as to the disinfection of the hands is altogether satisfactory, and we quite agree with him as to the employment of lubricants. "Avoid," he says, "the use of lubricants if possible. Carbolised vaseline is never safe, particularly when kept in a box into which dirty fingers are introduced from time to time." He prefers soap which has been boiled in the making as a lubricant if the outer layer is first washed off. We think, however, that perchloride glycerine (1 in 1000) is more convenient and reliable for this purpose.

In the chapter on Craniotomy and Embryotomy a Winter's modification of Auvard's combined cranioclast and cephalotribe is recommended, which is little known here and would seem to be worth trying. As regards the conditions necessary for performing craniotomy we do not quite agree with the author that the conjugata vera must measure more than two and a half inches. It is quite true that even in a flat pelvis with a true conjugate of that value craniotomy or cephalotripsy may be an extremely difficult operation, but it is not by any means always so, still less is it impossible to perform it. Nor can we agree that "the extraction of even a perforated head through a pelvis which is smaller than this is so dangerous that it should not be attempted." Perhaps this is meant to apply to those with only an ordinary amount of experience. But obstetricians of large experience at the present time have certainly not had reason to agree with the extract just quoted. Dr. Smyly tells us that he has with the greatest reluctance abandoned the use of chloroform in puerperal eclampsia. He thinks that chloroform does not save the patient's life, but on the contrary increases the chance of a fatal issue. He prefers morphia—half a grain is given hypodermically when the first fit occurs, and is followed every two hours by a quarter of a grain till the fits cease; not more than two grains are to be given in the twenty-four hours.

The book is clearly and concisely written. It appears to us admirably suited to the student; we may add that it also contains much that should make it useful to the practitioner.

JOURNALS, REVIEWS, &c.

The contents of the *Medical Magazine* for June are a little disappointing. A good paper by Mr. Poyntz Wright defines the various relative powers, duties, work, status, and mode of appointment of county medical officers of health, local district health officers, and sanitary inspectors, and will be found instructive reading; but is the author not a little hard upon district councils when he sweepingly speaks of their "bigoted prejudice," "supineness," and "inveterate obstinacy"? In our opinion these councils are remarkable chiefly for their willingness to be led. If the moving spirit is liberal-minded the council is on the side of the true public weal, but if the most important man on the council is a reactionary and ignorant man short-sighted methods will follow. Of the rest of the contents the most noticeable is a short article by Dr. Pye-Smith, F.R S., upon the complicated question of the University of London—a sequel to a previous contribution. The reader will find in this article a lucid statement of the present difficult situation.

Belgravia contains an informatory article from the pen of the editor, entitled "Sixty Years of Healing." The subject is the work of the London hospitals during the present reign, and there is no doubt that the publication of such papers in magazines stimulates popular charity by bringing home to general comprehension the magnitude of the work undertaken by the greatest of the metropolitan charities. The article is not exhaustive, and several institutions that have obtained no mention are much more worthy of notice than several whose claims are urged; but the information here collected concerning the income and expenditure of the hospitals is not often seen outside the columns of the medical journals, and will therefore appeal as something fresh to a lay public.

The *Inter-colonial Medical Journal of Australasia* contains among other papers an interesting communication by Dr. R. R. Stawell upon Thyroid Gland Extract as a Galactagogue. The value of a reliable medicine that would promote the secretion of milk would be immense, so that Dr. Stawell's results will have an interest for many practitioners. He details only nine cases, and, while admitting that this is but small clinical experience from which to generalise, concludes with some reservations that extract of thyroid gland is an efficient galactagogue. The dose given was from three to five tabloids per diem. In view of Dr. Stawell's results we think that medical men are justified in giving the treatment a trial.

In the *Phonographic Record of Clinical Teaching* for May Dr. Poore, in a lecture on Writer's Cramp, points out that the cause of the failure must be looked for anywhere "between the motor cortex and the tips of the fingers," and there is always some other defect than the inability to write. Dr. Poore has never examined a case without finding something definitely amiss, some wasting, tremor, paralysis, or something wrong with bones or ligaments, and the defect may be the forerunner of hemiplegia, a symptom of lateral sclerosis, or a result of lateral curvature of the spine. Mr. Jones Greer, writing from personal experience of West Africa, advises those who proceed to that white man's grave to maintain a high standard of personal health by the avoidance of excesses of all kinds, by keeping regular hours, by the use of the morning tub, and by boiling all drinking water if it appears of doubtful quality. On feeling out of sorts ten grains of quinine should be taken with a little whisky, and the patient should go to bed and perspire freely. In the treatment of the endemic fevers hyperpyrexia is best treated by antipyrin, phenacetin, and the cold bath, rather than by quinine. Not more than thirty grains of quinine should be given in twenty-four hours, and the quantity should be gradually diminished as the fever subsides. A shorthand edition of Dr. Gowers's lectures on the diagnosis of diseases of the brain, brought up to date, is announced as nearly ready for issue.

Hosted by Google

THE LANCET.

LONDON: SATURDAY, JUNE 12, 1897.

THE attention of Parliament is again to be directed to the question of lunacy reform. It has been found expedient further to amend the Lunacy Act of 1890, and a Bill has been issued with this object. The Act of 1890 was a measure of great importance to the public generally, and to those engaged in the care and treatment of the insane. Although defective in many respects it possessed one strong redeeming feature, for under its provisions the various Acts which had been passed from time to time were consolidated, and it became possible to ascertain with some degree of precision the relation of the law to the various classes of patients and to those responsible for its due observance. The Act was doubtless framed with good intentions, and in providing additional protection to the public, in multiplying the safeguards and privileges of patients, in placing the private patient on a nearer equality with the pauper so far as orders of detention are concerned, and in other ways its operation has been attended with beneficial results. On the other hand, owing to faulty draughtsmanship and to somewhat hasty legislation, many of its provisions are defective, others are irritating and vexatious, the meaning of many of the sections is by no means clear, and the increased burden of clerical work thrown upon the medical officers of asylums constitutes a grievance which time and custom have served only partly to modify. The necessity for further amendment is abundantly evident. The new Bill, which attempts to remedy a number of deficiencies, contains thirty-nine articles, or rather clauses, to which those engaged in asylum work must be prepared to subscribe, unless, indeed, the Bill is amended in its passage through the Legislature. It would be inexpedient to dwell at length on the changes dealt with in the various clauses, but some of the more salient features may be alluded to. It is proposed to curtail the time during which an urgency order is to remain in force from seven to four days. Further, the person who signs an urgency order and the medical practitioner who signs the medical certificate on which the urgency order is founded will in future be required to furnish an accompanying statement showing that it is necessary for the safety and proper treatment of the alleged lunatic, or for the safety of others, that he should be forthwith placed under care and treatment. The statement must also show fully and specifically why an urgency order is requisite. This regulation may be regarded as too stringent; it cannot fail to add to the perplexities and difficulties which so frequently confront the certifying practitioner, and it certainly will not tend to lessen his medico-legal responsibilities. Many medical men absolutely decline to sign lunacy certificates, and many more are likely to refuse should this rule come into force. In doing so they will act wisely both for the sake of their pockets and for their peace of mind.

One gratifying feature of the new Bill is the recognition of the claims of asylum officials to assured pensions and allowances. This important concession, too long withheld, will materially improve the prospects of the various grades of officials, and they will experience a feeling of relief from the state of uncertainty in which the question has been involved for such a length of time. Indirectly also the interests of the patients will be promoted, because fewer changes are likely to take place amongst the members of the subordinate staff, and the longer experience gained will render their services increasingly valuable. The proposed pension scheme is based upon the Poor-law Officers' Superannuation Act, 1896. It is directed that the provisions of the said Act shall apply to the visiting committee and to every officer of an asylum, in like manner, as nearly as may be, as they apply to guardians and their officers and servants, subject, however, to several modifications. A Secretary of State is substituted for the Local Government Board wherever the Local Government Board is referred to in the Poor-law Officers' Superannuation Act, 1896. The following are some of the principles contained in the Poor-law Act cited above—compulsory superannuation, compulsory retirement, transferred service to reckon as pension, power to add a number of years not exceeding ten in certain cases for peculiar professional qualifications or special circumstances, and power to grant gratuities in certain cases. Section 24 of the new Lunacy Bill empowers the visiting committee of an asylum to grant allowances or gratuities in cases of injury. When an officer of an asylum is injured in the actual discharge of his duty and through no fault of his own, the visiting committee may grant him an annual allowance, or in case of death from the injury they may grant to his widow or mother and to his children, or any of them, such annual allowance or gratuity as they, the visiting committee, may consider reasonable. Certain restrictions are appended as to the amount to be paid, but the scale seems just and fairly liberal. The pension scale is one-sixtieth for every year of service, the maximum of two-thirds not being attainable till after forty years' service; and there is an annual contribution to the pension fund of 2, 2½, and 3 per cent., according to the length of service. Any existing officer of an asylum may signify his intention within three months from the commencement of the new Act of not availing himself of its provisions. The discussion of the pension question some years back revealed very opposing views among asylum superintendents; whether they will be satisfied with the scheme set forth in the new Bill remains to be seen. Their claims to a higher rate of pension are deserving of every consideration, for their whole time is devoted to the service, and their duties are trying, onerous, and frequently dangerous; any endeavour on their part to get the Bill amended in this particular will, we trust, meet with deserved success.

It has been the custom for many years at the State Criminal Asylum, Broadmoor, to allow the patients a certain amount of remuneration for work done. Under Section 28 of the new Bill this principle has been

Hosted by Google

adopted; with the object of extending the useful occupations of patients and encouraging them to engage therein, the visiting committee are empowered to remunerate each pauper lunatic for his labour in the asylum at a rate not exceeding one-tenth of the sum at which the committee may estimate the value of the labour, and the remuneration so allowed shall be paid or applied for his benefit in such manner as the committee may direct. This is a wise and judicious step. No doubt the adoption of this principle will mean increased clerical work, but as substantial benefits will accrue to the patients no one will grudge the additional trouble. It is to be hoped that the money credited to patients will not be frittered away in providing them with small additional luxuries at their own request. Rather ought it to be allowed to accumulate and given to the patient when discharged on recovery, or distributed for the support of his family whilst he is under detention. The scheme, if well applied, ought to work beneficially; small difficulties will have to be surmounted in carrying it out, for a perverse lunatic with a balance at his credit on the asylum books is likely to prove on occasion a source of worry to the authorities. A long-recognised want is met by giving the Commissioners power to license houses to be used solely for the reception of idiots and imbeciles. In future all branch establishments must be registered. Heavy penalties are attached to any mis-statement wilfully or negligently made in connexion with an urgency order, or in any petition or reception order, or in any medical or other certificate. With regard to hospitals registered before the commencement of the Act of 1890, the Commissioners shall have power to certify the number of patients to be received, and dire consequences in the shape of fine or imprisonment, or both, are in store for the superintendents of such hospitals should they receive any patient or boarder in excess of the number so certified. Other important subjects are considered in the Bill—e.g., the appointment of magistrates, special inquiries as to lunatics, regulations as to infectious maladies, offences against patients, jurisdiction of Masters in Lunacy, &c. We regret that no mention is made of strengthening the Lunacy Commission by Deputy Medical Commissioners as in Scotland. There were six Commissioners in 1847, there are six now, yet the numbers of lunatics coming under their official supervision have increased sixfold in the space of fifty years.

The new Bill marks a great step in advance in the history of lunacy legislation; no doubt it is capable of amendment in various particulars, but on the whole it may be regarded as an honest attempt to simplify the working of a very difficult and a very intricate subject. We trust that it will prove an additional protection and a lasting advantage to all classes of the insane, and that those engaged in their care and treatment will "under its provisions" reap the benefits to which their arduous and difficult duties fully entitle them.

THE county of Surrey offers many facilities for an investigation into the influence of water-supplies upon health, as it comprises districts having mainly a river water-supply, as Weybridge and Walton; districts supplied from the lower greensand, as Dorking; and districts supplied from the chalk, as Reigate. The fact that these districts are somewhat sparsely populated and present somewhat varying social conditions furnishes difficulties and sources of fallacy, for which allowances must be made. The immediate occasion for Dr. SEATON'S report[1] appears to have been the apprehension created by the events of recent years at Worthing and Newport as to the dangers associated with public water-supplies from the chalk. It would appear that a water-supply from the chalk may be either the purest in respect of organic pollution or the foulest when exceptional and unexpected contamination occurs. The fact that sites on the chalk formations are not infrequently chosen for building large public institutions, which owing to their remoteness from any main system of sewerage are usually drained into soaking cesspools, while chalk in the neighbourhood not infrequently furnishes the public water-supply, gives the subject an added importance. It was brought prominently to the attention of the Surrey local authorities in 1894 by an application to the Local Government Board to borrow £2500 for the purpose of purchasing eight acres of land on Banstead Downs, whereon to erect an isolation hospital for infectious diseases. Objection was made to this site on behalf of the Sutton Water Company. This company derives its water from deep wells in the chalk two and a half miles distant from the site of the proposed fever hospital. Inasmuch as it was proposed to set one and a half acres of the site apart for the treatment of sewage by sub-irrigation and intermittent filtration of all the sewage—except that of enteric patients, which would be cremated—it is difficult to conceive how the water in the Sutton wells could be contaminated. Mr. BALDWIN LATHAM, however, was of opinion that impurities might be carried by fissures in the chalk to the wells of the company, and stated that he knew of fissures in the chalk much longer than two and a half miles. If such objections as this are to hold good, it evidently would be practically impossible to find a site for large public institutions upon the chalk at all. It is satisfactory therefore that the Local Government Board have granted the loan applied for in the above case. Cases like the preceding show the great [practical importance of the subject dealt with by Dr. SEATON. The statistical part of this report consists of a comparison of the death-rate per 1000 during two periods of ten years in four selected districts,—Chertsey (water-supply river, supplemented by shallow wells), Dorking (lower greensand), Reigate (largely chalk), and the Sutton, Carshalton, Leatherhead and Epsom district (almost entirely chalk). In the Chertsey district the death-rate from "fever" fell from 2·4 per 10,000 in 1876–85 to 0·8 in 1886–95; while during the same period it fell in the Dorking district from 1·8 to 0·46, in the Epsom district from 1·1 to 0·48, and in the Reigate district from 1·2 to 0·53.

From these data Dr. Seaton draws the conclusions that (*a*) a marked diminution of typhoid fever has occurred in all these districts; (*b*) that this diminution has been more marked in the districts deriving their water-supplies from the sand and river; but that (*c*) the figures relating to deaths are small, and do not admit of any decisive conclusion, further watching being required, so that conclusions may be revised in the light of the sickness returns now

[1] Annual Report of Dr. Seaton, the medical officer of the administrative county of Surrey.

Hosted by Google

becoming available. The following important general conclusion is stated: "So far as chalk water-supplies are concerned, it seems impossible to show that there has been any evidence of their having produced any notable ill-effects as regards typhoid fever." With this conclusion we entirely agree; but it appears to us that the above statistical data, though necessarily based on a somewhat scanty number of deaths, may serve to justify certain additional conclusions which Dr. SEATON has refrained from stating. In the first place, a comparison of the four districts shows that the districts having their water-supply from the chalk had a much lower death-rate from typhoid fever both in the first and in the second decennium than those deriving their water from other sources. Consequently the scope for improvement was much smaller in the chalk districts than in the others. That the mortality from typhoid in the Chertsey district should become reduced by about two-thirds might be expected with improved filtration of its river water, but that Epsom and Reigate should improve by about one-half without any filtration works, appears to indicate that causes are in operation other than the water-supply. In the second place, notwithstanding the smaller scope for improvement, the chalk water-supplies maintain in the second decennium their superiority over the non-chalk water-supplies, as indicated by mortality from typhoid fever. These facts appear to us to give additional importance to the part of Dr. SEATON'S report in which he discusses the question of the origin of typhoid fever apart from polluted water-supplies. The two great water-borne diseases are undoubtedly cholera and typhoid fever, and it has become the fashion to assume that the practical elimination of these diseases is entirely a question of the purity of the water-supply. This fashion Dr. SEATON very ably combats. "In 1879," he says "it had become evident to me that the persistence or endemic prevalence of typhoid fever year after year in districts which I knew to be above suspicion as regards purity of water-supply was incompatible with the assumption that typhoid fever was wholly, or almost wholly, water-borne. The further fact that this endemicity, or persistent prevalence, subsequently disappeared, apparently under the influence of improvements in sanitation (consisting mainly in the control of excremental or filth nuisances), quite unconnected with water-supplies, supplemented the negative evidence by that of a positive character." In England and Wales the death-rate per million from typhoid fever has declined from 277 in 1876-80 to 135 in 1891-94. It might, however, have been expected to be even greater than this, as Dr. SEATON points out, "had impurity of water-supply been the great main factor determining the presence of the disease."

With many other interesting points in this report we have not left ourselves space to deal. It may serve briefly to indicate a few of these. The copious water-bearing resources of the lower greensand in the Hind Head district, are emphasised. The report animadverts upon the reckless waste of water of high organic purity, obtained at the expense of pumping from deep subterranean sources. After a careful consideration of the relative value of the chemical and bacteriological examination of water, they are placed in their true position as "supplementary or auxiliary to inquiry of a medical nature which has generally been spoken of as epidemiology." With Dr. SEATON'S main conclusions most people will, we think, agree. Chalk water should be taken, when the cretaceous formation is on the surface, from sources as remote from the population as practicable. Soaking cesspools in water-bearing chalk or sand should be disallowed. The provision of sewerage systems is as necessary for the prevention of underground pollution in water-bearing strata as for the prevention of pollution of rivers. Finally, a systematic study of the movements of underground water in water-bearing strata is essential "in order to acquire better knowledge of the facts connected with this problem."

THE foundations of the antitoxin treatment were laid in 1890. In that year BEHRING and KITASATO, in their experimental researches on tetanus and diphtheria, discovered that the blood serum of animals rendered immune to the toxins of these diseases was capable of transmitting that immunity to other animals in which it was injected. The subsequent extension of this discovery to the actual arrest of the effects of the virus in inoculated animals led to the introduction of what has been called serum-therapeutics, and, in the case of diphtheria at least, the results of the treatment have been of a striking character. There has been ample opportunity for testing its efficacy, for diphtheria is a disease the prevalence of which is notorious and its share in child mortality is regrettably large. It may be recalled that at the International Congress of Hygiene at Budapest in 1894 Dr. ROUX, of Paris, adduced figures from his experience of the use of diphtheria antitoxic serum that at once attracted attention, for he stated that the continuous employment of this method of treating diphtheria at the Hôpital des Enfants Malades from February to July, 1894, had been followed by a reduction in the diphtheria mortality from 51·7 per cent.—the average of the previous five years—to 24·5 per cent., whereas the rate during the same months at the Hôpital Trousseau had been as high as 60 per cent. This statement alone sufficiently explains the welcome that was accorded to the new practice, and since that day the trials of the remedy, the conditions of its use, and many other facts concerning it have been published in all quarters of the globe. The testimony in its favour has been very large.

It is true, however, that here and there scepticism lingers, and figures have been quoted that seem to tell a different tale. Yet these contrary statements only serve to confirm the general opinion as to its value, for on scrutiny they are deprived of their significance. Thus in a monograph which has recently appeared Professor GANGHÖFNER,[1] of Prague, after detailing the facts advanced on all sides in support of the claims of the remedy, mentions that adverse opinions have been expressed by Professor SORENSEN, of Copenhagen, Professor KOHTS, of Strasburg, and Professor MÜLLER, of Halle. Dr. GANGHÖFNER, however, points out that in each instance conclusions have been drawn on too slender a basis and without adequate trial of the serum. Professor SORENSEN published two papers on

[1] Die Serum-behandlung der Diphtherie, von Dr. F. Ganghöfner (Heft I. des I. Supplementbandes des Handbuchs der speciellen Therapie innerer Krankheiten, herausgegeben von Dr. F. Penzoldt und Dr. R. Stintzing). Jena: G. Fischer. 1897.

Hosted by Google

the subject. In the first he contrasts his experience of 51 cases treated with the serum with 46 not so treated. In each series the mortality was 33 per cent., but, believing that the injections favoured a tendency to hæmorrhage, he seems to have used them with great caution, giving only small doses and often delaying the administration for days. Seeing that the success claimed for antitoxin mainly rests upon its earliest possible administration, and that, too, in ample dose, Professor SORENSEN'S negative results are not surprising. In a further return Professor SORENSEN records 9 deaths in 80 cases treated by the serum, but only 5 deaths in 140 without serum, but here the fallacy of selection renders the comparison useless, since the serum group contained twice as large a proportion of severe cases as the non-serum group, and, moreover, in 8 of the 9 fatal cases the serum was not injected until the third to the fifth day. Professor MÜLLER'S figures from the Halle surgical clinic, showing a mortality of 50 per cent. after tracheotomy amongst cases treated by serum, and of 40 per cent. amongst those not so treated, are also open to the criticism that in three-fourths of the former class the injections were delayed until the fourth or fifth day, and in some were of very small amount. The figures of Professor KOHTS, also based on the mortality after tracheotomy, showed but slight difference between the two classes, only his cases were too few in number to allow of any definite inference. Yet even here the mortality was much lower than the average for the preceding five years. But in all these comparative statistics there lurks the great fallacy due to the selection of cases submitted to antitoxin, some cases being untreated because of their mildness and others because the subjects were moribund on admission to hospital. This fallacy has been obviated in the statistics furnished by the medical superintendents of the hospitals of the Metropolitan Asylums Board by contrasting the relative mortality of all cases in the year 1896 (including those in which antitoxin was used and those in which it was not used) with that obtaining in the year preceding the introduction of the antitoxin treatment. The results of that comparison will be found in our last issue, and we may remark that they harmonise with the admitted fact that as a whole the death-rate from diphtheria, not only in London, but in all great centres, has fallen since the introduction of the remedy. As regards these statistics of the Metropolitan Asylums Board attention should be particularly directed to the most striking reduction of mortality effected in those patients coming early under treatment—a fact in favour of the remedial action of antitoxin which is demonstrated with especial force in the case of post-scarlatinal diphtheria, where it was mostly possible to carry out the administration very early indeed.

The utility of the treatment does not rest solely upon statistics, which, however carefully compiled, are open to fallacies due to the varied conditions which must of necessity prevail. It depends quite as much on the general consensus of opinion amongst those physicians who have fairly employed the serum that its use is followed by results no whit less certain than those which are ascribed to other drugs believed to have a specific action. Thus in prescribing antitoxin the physician feels sure of obtaining results as definite as those which ensue on the administration of quinine in ague or salicin in rheumatism. These effects consist in the main in the cessation of the spread of the diphtheritic membrane, its speedy deliquescence, together with a corresponding diminution in the intensity of the local inflammation. It is probably owing to this striking action of the arrest of the local process that under this treatment fewer cases of laryngeal diphtheria are now operated upon and that the percentage of recoveries after operation is larger than it was. How can this be explained except on the ground that the antitoxic serum acts directly upon the virus, preventing further mischief, although impotent to remove lesions already established by the poison? Nor can any objection to its use be based on the fact that certain complications seem to have become more frequent, for if through its agency in certain cases life is prolonged or preserved it would be in these very cases that one might expect the effects of the original virus to be most manifest. It is gratifying to have the assurance of the medical superintendents of the fever hospitals that in all their wide experience they have not met with any effects attributable to the injection itself which were of a nature to cause anxiety. It is true that since its general adoption there have been a few isolated instances of apparent fatal injury, but according to those who have investigated such cases they are one and all capable of other explanation. Even in the case of the most remarkable, and in its circumstances the most painful, of these, which occurred at Berlin last year, it is confidently affirmed that the fatal result must be attributed to cardiac paralysis excited by violent coughing from the inhalation of vomited matters in a susceptible subject, and not to the direct action of the serum or its injection. The subject is discussed in Professor GANGHÖFNER'S monograph, where the grounds for this conclusion are entered into. The case referred to was the more distressing from the fact that the injection was being practised, not for treatment, but for prophylaxis. It is, indeed, remarkable, considering the short time that has elapsed since the method was introduced and the necessarily tentative nature of its application, that so large an amount of confidence should have been awarded to it. This fact by itself surely testifies to its efficiency, and encourages the hope that with time and experience still more favourable results will be obtained.

Annotations.

"Ne quid nimis."

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON: A ROYAL JUBILEE PROCESSION PROGRAMME.

AN illustrated programme of the Royal Jubilee Procession, authorised by H.R.H. the Prince of Wales, will be published in aid of His Royal Highness's Hospital Fund for London, to which the entire profits will be devoted. The programme will contain detailed particulars of the procession, and sixty-four pages of illustrations will run throughout the pamphlet, with descriptive letterpress underneath. It will be published at one shilling, and will be on sale four or five days

Hosted by Google

before the day fixed for the procession, and will form, not only an illustrated guide, but an interesting memento of the day. Our readers, who will remember that last week we advocated exactly this scheme, will join with us in congratulating the officials of the Hospital Fund upon its adoption. We make bold to prophesy that their enterprise will receive substantial reward.

THE PRESENT OUTLOOK FOR THE YOUNG GENERAL PRACTITIONER.

CLUB practice at contract rates and the readiness with which hospitals admit patients combine to render the present outlook for the young general practitioner a far from hopeful one. "If he has means, if he has influence, his success may perhaps be assured; if, without these, he has the good fortune which is the lot of some men, he may find that the lines have fallen unto him in pleasant places; otherwise, he will find that the path is a very stony and a very steep one." So writes a correspondent to us with great truth, continuing: "These reflections are prompted by the fact that, in almost every issue of the journals, one reads that a motion has been passed at a given meeting condemning the acceptance of appointments of a specified nature. It is not fully realised that this affects almost solely the younger generation; it shuts against them another source of employment, already too scanty. The younger men are, as a rule, as eager as their elders to defend the best interests of the profession, but they have a right to ask that they may receive some return for their allegiance and may not be left thereby in a worse plight than formerly. For the settlement of the club question the active support of those who are fortunate enough to draw adequate fees is required, as well as a vigorous and united effort on the part of those already engaged in club practice. The reform of hospitals affects mainly consultants whose reputation is built up upon their hospital appointments; if these continue to place their own interests above those of the profession, they, and not the younger men, are to blame if the latter by these very abuses are driven to work on terms which they know are undignified, but which, by the stress of circumstances, they are compelled to accept."

THE PREVALENCE OF BOVINE TUBERCULOSIS AND ITS POSSIBLE EXTINCTION.

EVERY now and then public attention is called to the great and probably increasing prevalence of tuberculosis among cattle or, more correctly, among cows; for, if we had no more precise information, the disproportion between the 3 per cent. or less of carcasses in the meat markets in which the most careful inspection detects the evidence of disease and the 30 to 60 per cent. or more of cows on dairy farms in which the tuberculin test proves it to be present would be enough to show that tuberculosis is practically restricted to the latter. For the bullocks roaming in the open field or mountain pasture enjoy comparative exemption, and the tuberculous meat in the market is almost exclusively the flesh of cows fattened for the butcher either on account of their age and lessening yield of milk, or from their showing symptoms of the disease in its earlier, though easily recognised stages. There can be no doubt that, though their flesh may at this period be consumed without danger, its quality is deteriorated and its money value proportionately reduced, and that, though their milk may not be already infective, it may at any moment become so, should the glands of the udder be implicated. Unlike human beings, horses, and dogs, cows are notoriously stolid and undemonstrative even when suffering from grave disease, as tuberculosis or cancer; but it is strange that, on grounds both of danger to the public health and of pecuniary loss to the owners, farmers should be so apathetic as to the existence of a disease the aggregate loss from which must be greater than that caused by occasional outbreaks of such affections as pleuro-pneumonia. Tuberculosis, however, being, like other specific diseases, the microbes of which cannot perpetuate themselves for long out of the living body, contracted, whether directly or indirectly, solely by contact or association with other individuals already suffering from it, could be extinguished by rigid segregation and isolation of the healthy from the diseased. Such a procedure cannot indeed be seriously thought of with regard to human beings, and the futility of quarantine and sanitary cordons to arrest the spread of the highly infectious cattle plague has been as conspicuous here as in the case of cholera; but the conditions under which cows are kept on dairy farms, while calculated to favour, if not to render inevitable, the spread of any infectious disease, are also such as to present every facility for the elimination of tuberculosis, requiring as it does for its communication close and prolonged association. The observations of Koch on rodents, of Bang on cattle, and of Boltz on children, not to mention other names, furnish abundant evidence as to the extreme rarity of direct transmission from parent to offspring. Congenital tuberculosis is in the highest degree exceptional, the progeny of tuberculous parents being almost always born free from the disease and remaining so if removed to healthy surroundings immediately after birth; while in the characteristic reaction produced by the injection of tuberculin there is a well-nigh unerring means of diagnosing the existence of the disease, if not in its very earliest beginnings, at any rate at a stage when it is presumably not as yet communicable to others. Bang, whose procedure has been carried out successfully on numerous estates in Denmark, has shown that it is possible to eliminate tuberculosis from a herd in the course of two or three years, without having recourse to the drastic measures employed in the case of cattle plague and pleuro-pneumonia, and with little or no pecuniary loss at the time, but with a great gain in the end. His method consists in testing the entire stock by one or two injections, and the removal of all those that react to a separate establishment at as great a distance from the others as possible. All new purchases are tested in like manner, and the process of inoculation of the apparently healthy animals, with the separation of those that react, is repeated every six months until they cease to give any result. Those that give evidence of being tuberculous are fattened for the butcher, but if already in calf or but very slightly diseased they may be allowed to calve once, or perhaps twice, provided their milk is not used for any purpose except for feeding pigs, and that after being boiled, their calves being transferred at birth to the healthy establishment and tested when about six months old. If public opinion in this country be not ripe for compulsory legislation, it is much to be desired that the county councils should at any rate encourage the practice by diffusing information on the subject and by providing free of cost a supply of tuberculin and the service of expert veterinary surgeons to perform the inoculations and direct the subsequent arrangements.

KISSING THE BOOK.

AS mentioned in THE LANCET of May 29th, p. 1518, the subject of the administration of oaths has again come before the House of Commons in the form of a question put by Sir Walter Foster to the Attorney-General. While it is satisfactory to notice that the learned gentleman promised to consider whether any further amendment of the law was required, this promise was preceded by two statements, both of which are open to criticism. The first is Sir Richard Webster's expression of opinion that the fear of infection alluded to in Sir Walter Foster's question had

Hosted by Google

been somewhat exaggerated. Even if this were simply a matter of opinion it is surely rather one to be decided by the medical profession than by the lawyers. But if Sir Richard Webster will devote an hour of his leisure during the Whitsun recess to the practical study of the administration of oaths as seen during the hearing of the night charges in any of the metropolitan police-courts he may be induced to see that it is a matter of fact, rather than of opinion, which cannot be exaggerated. Let him carefully scrutinise each witness as he or she comes up to the book to be sworn and ask himself if he would like to touch or kiss the same book? Let him also ask what will be the effect if one of these days the fact of infection with some disease should be traced to the book beyond all doubt? Will the infected witness have his remedy in an action for damages, and, if so, against whom? Moreover, Sir Richard Webster pointed out that "under the provisions of the Oaths Act of 1888 witnesses were now permitted to take the oath in the Scotch form, in which it was unnecessary to kiss the book." But he must have known perfectly well when he made this statement that numerous cases have been published in THE LANCET and in the daily press in which witnesses (chiefly medical) have been denied this legal right by those whose duty it was to administer it, these latter having been wholly ignorant of the Act referred to. And even when the Act was known, the form of Scotch oath could not be found, though each official to whom this duty is entrusted ought to have it at his fingers' ends quite as readily as the English form. Again, the Attorney-General must be perfectly aware that with very few exceptions the average witness knows no more about the Scotch oath and the fifth section of the Oaths Act, 1888, than he does of the man in the moon, the Act being to him as veritable a dead letter as if it had never been passed. Nothing but its total abolition can change the ordinary form of English oath, and we trust that a Bill for this purpose will be introduced very soon after the reassembling of Parliament. If it is not, we trust that Sir Walter Foster will repeat his question and be warmly supported by other members.

STREET RUFFIANISM.

IN spite of the general prevalence of education and of orderly habits we have not yet got rid of the juvenile ruffian. The youth of seventeen who was convicted of manslaughter last Monday for having shot a child in a street fight was an example of this class. Not only so, but he was a member of a gang most of whom carried revolvers and employed their leisure in street fighting. Under the circumstances it is, indeed, remarkable that life has not been taken long ago by these young scoundrels. It is at least equally remarkable that such revivals of savagery as this have existed and even thriven in our midst in spite of all the machinery of law and order. It is easy enough to account for the origin of this unmanly and unboyish barbarism. We have only to allow the passionate hot-headedness of youth to run unchecked and untrained in the channels of idleness in order to witness the effects of its misguidance. There is much, moreover, in city life which induces temptation and fosters evil. We must look for correctives to the steadying influence of school and of work, to sound home training at the hands of the parents, to the healthy regulation of amusement—forces which, though as yet inadequate, are already active. While accepting all these aids, however, and admitting their remedial value, we must allow that a present and more rapid means of relief is indispensable. Riot on a large scale is promptly repressed. Why, then, should not the same course be followed with its lesser developments? Had the practice of gang fighting been put down in Clerkenwell at its outset we should not now have to remember the fatal encounter which occurred a week since. It is to be hoped that after this boy riots will be treated with summary and exemplary severity and with a primary view to their prevention. Corporal punishment should not be omitted whatever the qualms of the modern conscience in regard to it. An important step, in our opinion, would be to make the bearing of pistols or other arms by boys under a given age a criminal offence.

CHOLECYSTITIS IN TYPHOID FEVER.

As a rare complication of typhoid fever cholecystitis has long been observed; but the number of recorded cases is still very small (about forty), and it is only during the last few years that our knowledge of the subject has developed. Dr. Lawrence Mason has recently published a valuable article on the subject.[1] The pathological changes are variable, the gall-bladder may contain serous fluid, pus, or membranous exudation; ulcers often multiple, may form and cause perforation; abscess may occur in the coats. The inflammation is the result of infection of the gall-bladder by the typhoid bacillus, which was first proved by Gilbert and Girode.[2] Subsequently Chiari reported to the eleventh International Medical Congress the results of necropsies on 22 cases of typhoid fever. In 3 only were typhoid bacilli absent from the gall-bladder; in 15 they were present apart from other microbes and the number was often great. Cholecystitis had occurred in 13. He concludes that the occurrence of bacilli in the gall-bladder is the rule in typhoid fever. This inference seems to us scarcely justifiable; the condition of the gall-bladder in fatal cases cannot be fairly taken to represent that in all. *A priori* we should expect, if the extent of infection of the organism is variable, as it appears to be, a more widespread infection in fatal than in non-fatal cases. However, liberally discounting his inference, his facts seem to show that cholecystitis in typhoid fever is not the rare event indicated by the number of recorded cases. Gall-stones are distinctly a predisposing cause. They have been found in about one-fourth of the necropsies. Conversely, there is some evidence that typhoid infection may cause their formation. Dr. Dufourt of Vichy found that 19 patients had their first attack of colic after severe typhoid fever. It occurred after the fever as follows: in the second month in 2 cases, in the third in 6, in the fourth in 3, in the fifth in 1, and in the tenth or later in the remainder. Whether the bacilli cause a chemical precipitate or act as nuclei themselves, or whether stagnation of the bile as the result of the fever is the cause of the production is unknown. Typhoid cholecystitis often produces no noticeable symptoms. The general condition of the patient often prevents any complaint. In more than half the recorded cases nothing unusual was observed. On the other hand, a characteristic picture may be presented—pain in the region of the gall-bladder and under the angle of the scapula and a very tender swelling in the former situation, dull and giving doubtful fluctuation and sometimes visible. Perforation gives rise to symptoms of general or local peritonitis. The prognosis is unfavourable if there is much distension. The treatment consists in relieving the pain by opium, tapping the gall-bladder if necessary, and the performance of laparotomy if perforation has occurred. Dr. Mason describes a case of his own so far unique. A woman towards the end of the third week of typhoid fever complained of increasing abdominal pain in the right hypochondrium, where a tumour four inches in diameter developed, extending from the costal border towards the umbilicus, and causing a visible, very tender swelling. She became partially collapsed, and rupture

[1] Boston Medical and Surgical Journal, May 13th, 1897.
[2] La Semaine Médicale, 1890, No. 58.

Hosted by Google

seemed imminent. Aspiration was performed one inch below the ribs, and four and a half inches from the umbilicus. Three and a half ounces of sero-purulent fluid were withdrawn. Relief of pain was immediate, and recovery followed. The typhoid bacillus was cultivated from the fluid removed. We published some time ago a case, in which laparatomy was successfully performed for typhoid perforation of the gall-bladder.[3] A woman, aged thirty-one years, on the eleventh day of an attack of typhoid fever had severe pain in the upper part of the abdomen, with semi-collapse, thought to be due to perforation. She recovered, and became convalescent. At the end of the sixth week, another sudden accession of pain and tenderness in the right hypochondrium occurred, where a dull tumour, the size of an orange, appeared. Again intestinal perforation was diagnosed, and the condition regarded as nearly hopeless. Next day her general condition was better, but the abdominal symptoms were worse, there being increased tympanites and immobility of the abdominal wall. Laparotomy showed turbid fluid in the right hypochondrium, but no intestinal perforation. The gall-bladder was deeply inflamed, of a dark plum colour, thickened, adherent, and distended. Near the neck was an ulcer of the size of a threepenny-piece, of typhoid appearance, and with a small perforation through which oozed the contents. The gall-bladder was opened and emptied of an ounce and a half of thick offensive pus. It was found impossible to unite the edges of the ulcer by Lembert's method. The edges of the incision in the fundus were, therefore, attached to the parietal peritoneum and drainage provided for. Recovery followed.

COLLECTIVE INVESTIGATION OF THE ANTITOXIN TREATMENT.

OUR New York correspondent writes:—The American Pædiatric Society's report on the collective investigation of the antitoxin treatment of laryngeal diphtheria in private practice for 1896-97 was submitted to the society at its late meeting at Washington. In this second and supplementary investigation the aim has been to ascertain—(1) what percentage of cases of laryngeal diphtheria recover without operation under antitoxin treatment; and (2) what percentage of cases operated on recover. The report now submitted may properly be limited to answering these two inquiries. Sixty thousand circulars were distributed throughout the United States and Canada. The whole number of cases in this report are 1704, with a mortality of 21·12 per cent. (360 deaths). The following were the operations employed: (*a*) Intubation in 637 cases; mortality, 26·05 per cent. (166 deaths); (*b*) tracheotomy in twenty cases; mortality, 45 per cent. (9 deaths); and (*c*) intubation and tracheotomy in 11 cases; mortality, 63·63 per cent. (7 deaths). Non-operation cases, 1036, 60·79 per cent. of all cases; mortality, 17·18 per cent. (178 deaths). Operation cases, 668, or 39·21 per cent. of all cases; mortality, 27·24 per cent. (182 deaths). Two facts may be recalled in connexion with this paragraph. First, that before the use of antitoxin it was estimated that 90 per cent. of cases of laryngeal diphtheria required operation, whereas now, with the use of antitoxin, 39·21 per cent. require it. Secondly, that the percentage of figures has been reversed, formerly 27 per cent. approximately representing the recoveries, while now, under antitoxin treatment, 27 represents the mortality. To put it in other words, before the use of antitoxin 27 per cent. recovered; now 73 per cent. recover, and this in the severest type of diphtheria. The present report will strike many as revealing a mortality a little too large in each of the two classes. The mortality is large—larger than the personal experience in private practice of many would expect. The reasons for this are—(1) that antitoxin is still used too late, either from procrastination on the part of the physician or objection on the part of the friends; or (2) in a half-hearted way, which shows itself in doses from one-tenth to one-fourth as large as they should be. In truth, both the physicians and the friends of the patient are timid. This report, it must be admitted, shows too large a mortality. In the opinion of the committee it is a larger mortality than will ever be shown again. Antitoxin is gradually being used earlier in the disease, and it will soon be used in sufficient doses. To the society the committee desires to say that it has sought to carry out its wishes in putting antitoxin on trial, and to accept no testimony that did not bear the stamp of reliability; that it has employed the methods approved in the case of the first investigation and report; and that it has confined its work to definitely answering the main questions which the society and profession now have in mind. Points that were settled in the first report, and have since been corroborated by general medical literature, are not again taken up. The committee states that the three most valuable points established in this eleven months' work are—(1) the mortality of laryngeal diphtheria at present rests at 21·12 per cent.; (2) that 60 per cent. approximately have not required intubation; and (3) that the mortality of cases operated on is at present 27·24 per cent.

[3] Mr. Monier-Williams and Mr. Marmaduke Sheild, THE LANCET, March 2nd, 1895, p. 534.

PILGRIMS AND QUARANTINE.

THREE weeks ago the great festival at Mecca took place; the faithful assembled in their thousands and the usual sacrifice of animals was made. The health of the immense concourse of pilgrims was officially declared to be perfectly good, and searching telegrams from Egypt could not discover any unusual amount of diarrhœa or dysentery among the worshippers. But "pilgrim diarrhœa" has become an annual factor which has never yet been dealt with, and there are some who suspect that cholera for the last few years has been endemic in the holy places and presumably in the holiest of all, Mecca, with its well-known water from the Zem-Zem well. This is only conjecture, for no reliable clinical evidence, and absolutely no bacteriological or pathological information, ever reaches us from the Haj. It is idle to expect Turkey to initiate any reform, but is it not time for Europe to insist upon this pilgrimage being conducted on cleanly and decent lines? India possesses many trained Mussulman physicians, and though her bacteriology is as yet in its infancy she might have done much in all these years past to control her share of the pilgrimage. Cairo, Constantinople, and Algiers all boast of Mohammedan bacteriologists, and there is no reason why one of them should not be sent both to Mecca and Jeddah to work before and during the next pilgrim season. The Great Powers up to the present have treated this annual Haj with Oriental apathy, and have contented themselves with wrangling over theoretical questions at occasional congresses.

SPECIAL INSTRUCTION FOR FEEBLE-MINDED CHILDREN UNDER THE POOR-LAW.

THE Departmental Committee of the Local Government Board in their report on the London district schools pointed out that feeble-minded children are necessarily admitted to the Poor-law schools, and evidence was brought forward showing that about 1 per cent. of children of school age are so far subnormal in physical and mental power as to require special training. A recent order of the Local Government Board places these children for the future under the care of the Sick Asylums Board for the metropolitan area, and that public body will apparently have to provide for their care and education. An objection has been raised that by such a

Hosted by Google

transfer these children will be removed from their fellows and placed under a board whose only educational work is in the care of children of unsound mind. It is thought that the arrangements may resemble too much those of an asylum. The managers of the Kensington and Chelsea schools at Banstead wish to make provision for the feeble-minded children under their care, and propose to allot a "special class-room," where a dozen such children, who have been selected with care, may receive special instruction. After some delay the Local Government Board has sanctioned the appointment of a teacher to take educational charge of these children. It is not proposed to separate the children, who will reside in the cottage homes, but to arrange that as now in domestic life, sleeping, and meals, they may join in with the others as much as possible. In school time they will go to the "special class," where they will receive a modified form of Kindergarten training and appropriate physical exercises. The experiment is inexpensive and well worth trying. We hope it may succeed.

RECURRENT MEASLES.

IT is, we suppose, admitted that in none of the infective diseases does one attack confer absolute immunity from a second; but apart from small-pox there are but few available data for estimating the comparative frequency with which such second attacks occur. Dr. Pole Kitson, of Cleobury Mortimer, Salop, reports that in a recent outbreak of measles in his district several examples of this somewhat unusual character took place. In particular he cites one in which several members of one family were attacked with measles in March and again in May or the end of April. He gives details of one of these patients whom he first saw on March 3rd with well-marked eruption and catarrhal symptoms. Recovery followed in a fortnight, but on May 4th Dr. Kitson was again summoned to attend him for an illness in which all the previous symptoms were repeated. Such a case can hardly be regarded as a "relapse," and if the later illness were indeed measles it points to a very brief immunity from infection, and it is not a little remarkable that other members of the same family should also have been again infected. We have assumed that the diagnosis was accurate, for in all such cases, as remarked by a recent writer, there is a possibility of "the first or the second eruption being in reality that of 'German measles.'" To adopt such an explanation, however, in the present instance, in view of the fact that measles was prevalent in the district, would be begging the question; and it would be preferable to admit that under certain conditions the protection afforded by a single attack does not always secure the individual against further infection.

THE Drapers' Company with great munificence have offered to erect a new building for the accommodation of the Radcliffe Library at Oxford, at a cost of £15,000, from plans to be submitted by Mr. T. G. Jackson, R.A., for the approval of the University authorities.

THE death of Professor Charteris, of Glasgow University, is announced. He had been in indifferent health since the end of March, and had not conducted his class during the current summer session.

H.R.H. THE PRINCE OF WALES will open the Brook Fever Hospital, erected by the Metropolitan Asylums Board at Hither-green. The date of the ceremony has not yet been fixed.

SICILY

AS A HEALTH RESORT.

II.[1]

The Factors which determine Climate.—Characteristics of the Mediterranean Climate.—Prevailing Winds in Sicily.—The Sirocco.—The Sicilian Climate essentially Insular.—Meteorological Returns of (1) Palermo, (2) Catania, (3) Syracuse, (4) Girgenti, (5) Termini, (6) Taormina.—Sketch of a Year's Weather at Palermo.

THE last article contained a short sketch of the features of the Sicilian climate in general. The present article will be devoted to a more detailed consideration of the same subject, and to the special meteorological characteristics of the different localities—Palermo, Catania, Syracuse, Girgenti, Termini, and Taormina.

The factors which determine climate are the following:—(1) Latitude; (2) elevation above the sea level; (3) prevailing winds; (4) ocean currents; (5) conditions of local shelter or exposure; (6) proximity of warm or cold seas, deserts, snowfields, &c.; and (7) geological formation and conditions of soil.

Sicily lies between 36° 38′ and 38° 19′ of north latitude. Cape Passaro, the extreme southern point of the island, is farther south than Algiers or Tunis, a fact that may serve to emphasise the point that the climatological relations of Sicily with the African continent are intimate and important. As has already been observed, a strait of shallow water, about eighty miles wide, separates Sicily on the west from Tunisia. Lying in the centre of the Mediterranean, Sicily possesses the typical Mediterranean climate, of which the leading features are warmth, mildness, brightness, moderate humidity, a high proportion of fine weather, and comparative immunity from mist, fog, sharp winds, and winter cold. The prevailing winds from October to March are from the west-south-west, hence an equatorial marine current which brings rain. From May to September north-easterly polar currents prevail, and for many consecutive weeks the weather is practically rainless. At the season of the equinoxes there is a conflict between the equatorial currents and the polar currents, with windy and unsettled weather. The sirocco, a south-easterly wind from the southern deserts, blows at all seasons, but it is rare in winter, and at this season its disagreeable features are insignificant. It is comparatively common at the turn of the season in April and May, and again in September and October, while it also occurs, though more rarely, during the summer months. The sirocco is a hot, dry wind, obscuring the sky and bringing clouds of dust. During its prevalence the thermometer sometimes rises to from 100° to 105° F. (= 37·8° to 40·6° C.) in the shade, but this is rare. It lasts one, two, or at most three days, and is usually followed by refreshing rains. Its enervating effects are more felt by the healthy than by the ailing, and some invalids (especially some *poitrinaires*) feel unusually well during the prevalence of the sirocco. Though disagreeable it is not an unhealthy wind, and it does not aggravate existing disease or raise the general rate of mortality.

It would not appear that marine currents exercise any considerable influence upon the climate of Sicily. Conditions of local shelter or exposure have important bearings upon the special features of some of the Sicilian resorts. Palermo owes some of the special characteristics of its climate to its ring of enclosing mountains. Catania is affected by the proximity of the Etna snowfields. Girgenti faces Tunisia and feels more fully than other parts of the island the influence of the African continent.

The influence of the encircling Mediterranean is a dominant factor in determining the character of the Sicilian climate. The Mediterranean is an expanse of comparatively warm water, and as Dr. Marcet has shown, the temperature of

[1] No. I. was published in THE LANCET of June 5th, 1897.

Hosted by Google

the surface of the sea has a mean excess in places of about 12° F. (=6·6° C.) over the minimum temperature of the air. Sicily is thus laved on all sides at all seasons by a warm sea, which retains its summer heat until at least the end of November. Occasion will hereafter be taken to compare and contrast the climate of Sicily with that of the Riviera. It is sufficient to remark here that while the climate of the Riviera owes its characteristics partly to the influence of the Mediterranean and partly to that of continental Europe, Sicily owes its climatic peculiarities predominantly to the influence of the Mediterranean and in a minor degree to the influence of the African continent. It does not feel the influence of continental Europe to any appreciable degree. From Sicily to Cape Bon in Tunisia is a distance of less than 140 kilometres, while from Sicily to Genoa is a distance of 780 kilometres. Thus, much is heard in Sicily of the sirocco, but nothing of the mistral or the bise. Hence the rainless summer of Sicily, the absence of frost, snow, and winter cold, the rarity of cold, the rarity of cold winds from any quarter, the high average of fine weather, the marked equability of temperature. The Etna snowfields exercise some slight effect upon local meteorological conditions at Catania, Aci Reale, and Taormina. Otherwise their influence is unimportant. The geological conditions in Sicily are on the whole favourable in their influence upon climate. The surface of the country is in large part composed of tertiary limestone. Alluvial soil and marshy lands occur, but are not widely distributed.

The meteorological characteristics of the various localities will now be considered more in detail.

1.—PALERMO.

Palermo lies on the west side of the Bay of Palermo, and is surrounded by a rich plain, the fertile Conca d'Oro or Golden Shell, which is enclosed by an amphitheatre of lofty mountains, the highest summit, Monte Cuccio, attaining an altitude of 3445 ft. The town is protected on the north by the imposing mass of Monte Pellegrino, but is exposed on the north-east. Palermo owes the special features of its climate—viz., its mildness, equability, and comparatively large rainfall—in considerable degree to the influence of the encircling mountains, which intercept the moisture-laden winds from the south-west and west-south-west and cause a considerable precipitation of rain upon the "agro palermitano," or Conca d'Oro. The mean annual temperature of Palermo is 18·15° C. (= 64·6° F.), while that of Catania is 18° C. (= 64·4° F.), of Syracuse 17·4° C. (= 63·3° F.), and of Girgenti 17·9° C. (= 64·2° F.). These are the official figures. Assuming their correctness it would appear that Palermo, in spite of its geographical situation, has a higher mean annual temperature than the other chief localities in the island. It owes this peculiarity, probably, to the conditions of local shelter already referred to. Palermo has an average daily variation of only 6·7° C. (= 12·8° F.), as against 7·7° C. (= 13·8° F.) for Catania. It is warmer in winter and cooler in summer than Catania, and its climate may be regarded as one of the most equable in Sicily. The mean temperature of the months of the year at Palermo is as follows :—

	Degrees.		Degrees.
January,	10·89 C. = 51·60 F.	July,	26·03 C. = 78·85 F.
February,	11·61 C. = 52·90 F.	August,	26·16 C. = 79·09 F.
March,	13·34 C. = 56·01 F.	September,	23·93 C. = 75·07 F.
April,	15·56 C. = 60·01 F.	October,	20·31 C. = 68·56 F.
May,	18·89 C. = 66·00 F.	November,	15·88 C. = 60·58 F.
June,	22·67 C. = 72·81 F.	December,	12·53 C. = 54·55 F.

The mean average temperature of the invalid season—Nov. 1st to April 30th—is 13·30° C. at Palermo, which is almost equivalent to 56° F. This figure may be contrasted with the mean temperature at London during the same period, which is 41·8° F. (=5·4° C.), and at Cannes—viz., 50·1° F. (=100° C.). The absence of winter cold is brought out clearly by the returns of the Palermo Meteorological Observatory. In the decennial period 1880–89 there were only two years—viz., 1882 and 1883—in which the thermometer touched freezing point on the terrace of the Observatory. In the other years the minimum temperature registered varied from about 32·5° F. to 37° F. (= 0° C. to nearly 3° C.). The mean temperature of the coldest month at Palermo, January—viz., 10·89° C. (= 51·6° F.)—may be compared with the mean temperature of the same month at Ventnor—viz., 41·6° F. (=5·3° C.); at Cannes—viz., 49·6° F. (=9·8° C.); and at Cairo—viz., 53·6° F. (=12·0° C.).

The mean relative humidity of the air at Palermo is 65·4 per cent. (saturation = 100 per cent.). The humidity of the air is greatest in November (69·3 per cent.), December (70·7 per cent.), and January (69·9 per cent.); least in June (63·4 per cent.), July (60·2 per cent.), and August (59·7 per cent.). As pointed out in the first article of this series these figures indicate a moderate, not a high, degree of humidity. The proportion of fine, sunny days on the one hand, and of cloudy or rainy days on the other, is a matter of the first importance in connexion with any health resort. The following are the average annual figures for Palermo :—

1. "Giorni sereni"—i.e., days of cloudless sunshine	167	= 229 fine days per annum.
2. "Giorni misti"—i.e., days of combined cloud and sunshine	62	
3. "Giorni coperti"—i.e., cloudy days	136	
4. "Giorni plovosi"—i.e., days with some rain	116	
5. "Giorni ventosi"—i.e., windy days	33	

The average annual rainfall is 758·68 mm. (=29·87 in.) and the average precipitation per month is as follows :—

Millimetres.		Millimetres.		Millimetres.
January, 118·20	May,	33·55	September,	42·16
February, 74·86	June,	12·57	October,	100·05
March, 72·05	July,	5·96	November,	102·70
April, 66·96	August,	13·13	December,	117·49

It will be thus seen that Palermo has a considerable rainfall (758·68 mm. = 29·87 in.), and that the fall is chiefly in the winter months.

The following may serve as a slight sketch of the usual climatic conditions throughout the year at Palermo. Summer sets in towards the end of May and lasts until September. This is the dry season, and the rainfall is very small. It is not uncommon for an entire month to pass without any collectable rainfall. The mean temperature varies from 19° to 26° C. (= 66·2 to 78·8 F.), and with the exception of an occasional day of sirocco, when the maximum temperature may exceed 100° F., (= 37·8° C.) high temperatures are rare. There is great power of sun-heat from 11 A.M., to 5 P.M., but the mornings, evenings, and night are moderately cool. The sky is for the most part cloudless, the atmosphere is calm except when the sirocco is blowing, and the prevailing wind is N.E., with occasional variations to W.S.W. The settled summer weather begins to break in September. The wind changes frequently and is sometimes boisterous. The sirocco becomes more frequent, and the amount of cloud and of rain increases. The weather is often close and relaxing, and on the whole September is perhaps the least pleasant month of the year. In October the winds settle to W.S.W., from which quarter they continue to blow until April, with occasional changes to N.N.E. and S.E. The temperature falls and rain becomes more frequent. November presents a similar condition of things, with a further fall of temperature and a slight increase of rainfall. St. Martin's summer ("l'estate di San Martino") is sometimes well marked. December and January have a considerable rainfall and a somewhat high proportion of cloudy days. There is little real cold, the thermometer only very exceptionally touching freezing point, and the amount of snow being confined to a slight shower four or five times in the season. A slight film of ice occasionally forms on standing water, but this is rare. February and March often bring fine, bright, settled weather, with a very agreeable temperature and a large proportion of charming days. At this season the weather in Sicily generally is often much the best in Europe. There are no cold winds comparable to the mistral or the bise, though the north-east wind or greco may be felt rather sharply at times by the more delicate invalids. April marks the transition season, and the weather is somewhat less settled. Sirocco days become more frequent. The weather is, however, often charming in the highest degree, the air is delightfully soft and balmy, there is no unpleasant heat or treacherous cold, and the aspect of the country, with its waving corn crops, luxuriant orange groves, and innumerable multitude of wild flowers, is truly "incantevole" (enchanting)—to use the favourite term of the Sicilian meteorologists. In May the temperature rises steadily, rainy days become rare, the winds settle in the north-east, and by the end of the month the cloudless, rainless, Sicilian summer has fairly commenced.

2.—CATANIA.

Having dealt fully with the climatic conditions of Palermo those of the other chief localities of the island may be more briefly considered. The mean annual temperature of

Hosted by Google

Catania is 18° C. (= 64·4° F.). The mean temperature of the various months is as follows :—

	Degrees.		Degrees.
January,	9·73 C. = 49·51 F.	July,	26·65 C. = 79·97 F.
February,	10·93 C. = 51·67 F.	August,	26·28 C. = 79·30 F.
March,	12·51 C. = 54·52 F.	September,	24·61 C. = 76 30 F.
April,	14·84 C. = 58·71 F.	October,	20·81 C. = 69 46 F.
May,	18·35 C. = 65·03 F.	November,	16·14 C. = 61·05 F.
June,	23·02 C. = 73·44 F.	December,	12·09 C. = 53·76 F.

The mean temperature of the different seasons is as follows :—

	Degrees.		Degrees.
Winter...	10·88 C. = 51·58 F.	Summer...	25·31 C. = 77·56 F.
Spring...	15·26 C. = 59·47 F.	Autumn...	20·53 C. = 68 95 F.

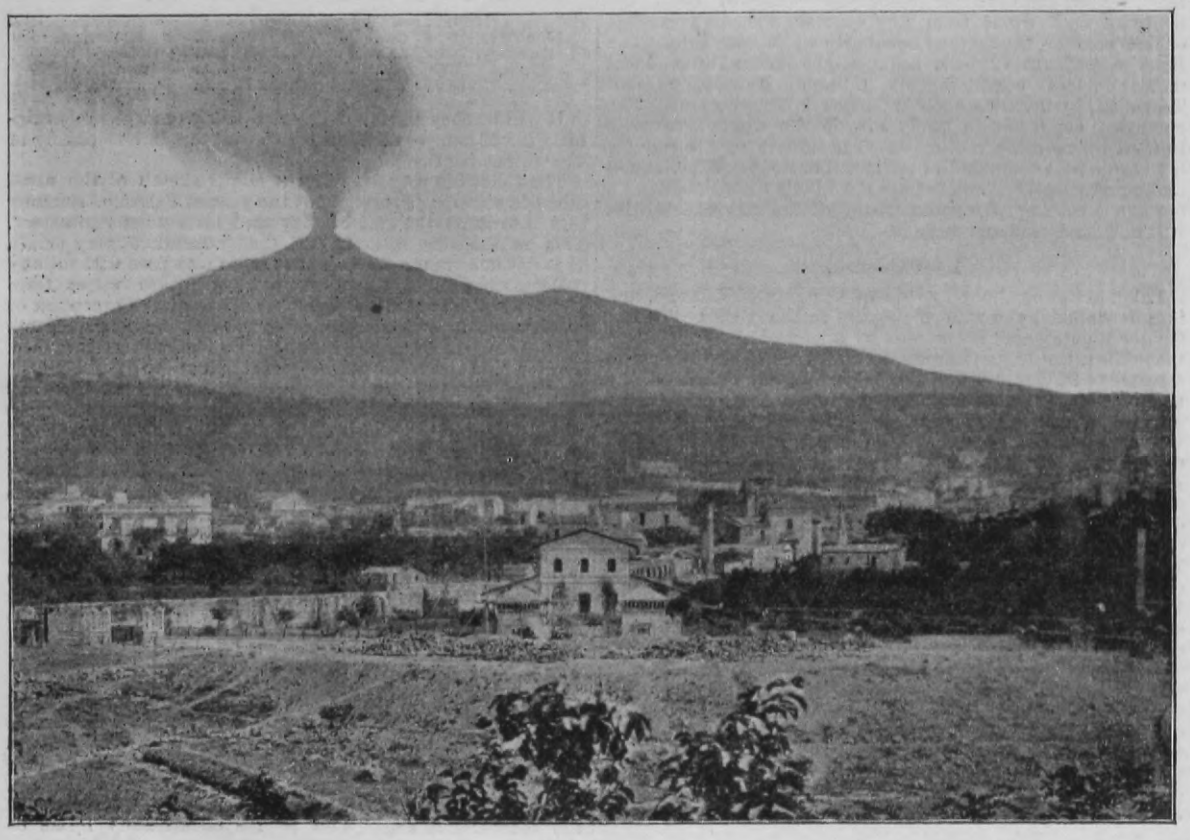
The mean daily range of temperature is 7·7° C. (= 13·8° F.). The range is greatest in summer, least in November and December. The mean relative humidity is 61·0 (saturation = 100). The average annual rainfall is 542·7 mm. (= 21·32 in.). The average amount of daily sunshine is 0 62 per cent. The following is the average state of the weather :—

"Giorni sereni" (days of cloudless sunshine) ...	164	= 282 fine days per annum.
"Giorni misti" (days of combined cloud and sunshine)	118	
"Giorni coperti" (cloudy days)	83	
"Giorni piovosi" (days with rain)	86	

Snow falls on an average one day in the year, frost occurs once or twice a year, hail falls on from 3 to 4 days, and storms occur on about 8 or 9 days. Cold winds from the Etna snowfields are not frequent or troublesome, but dust from the lava is sometimes a source of annoyance.

A comparison of these figures with those of Palermo shows some interesting points of contrast. The climate of Catania is drier and brighter than that of Palermo, the rainfall is one-third less, the relative humidity is less by 4·4 per cent., the proportion of days of cloudless sunshine is about the same as Palermo, but the "giorni misti" are more numerous by 56, the mean daily range of temperature is greater by 1° C., and the difference between the hottest and the coldest month is more marked. It would thus appear that Catania has a less equable climate than Palermo, but that it has a decided superiority in the proportion of fine weather and in the lower humidity and smaller rainfall. It is probable that the proximity of Mount Etna is a chief factor in the explanation of these peculiarities.

3.—SYRACUSE.



The following figures refer to the year 1896 unless otherwise stated. The mean temperature for the year was 17·4° C. (= 63·3 F.). The mean temperature for the various months was as follows :—

	Degrees.		Degrees.
January,	9·8 C. = 49·6 F.	July,	26·1 C. = 79·0 F.
February,	10·2 C. = 50·3 F.	August,	25·5 C. = 77·9 F.
March,	12·9 C. = 55·2 F.	September,	23·8 C. = 74·9 F.
April,	*12·5 C. = 54·5 F.	October,	20·2 C. = 68·4 F.
May,	16 8 C. = 62·2 F.	November,	16·5 C. = 61·7 F.
June,	22 1 C. = 71·8 F.	December,	12 6 C. = 54·7 F.

* This is the official figure. It is probably a slip for 14·5.

The lowest temperature recorded was 2 9° C. (= 37·2° F.), which occurred in the month of January. The mean relative humidity was 70. The number of days with rain was 85. The number of windy days was 109. The average rainfall (1874–1896) was 570·8 mm. = 22·7 in. The number of "giorni sereni" and "giorni misti" is not stated, but the proportion is probably high.

The above returns being for the most part for one year have but a limited value. The general characters of the climate of Syracuse are, however, clear. It has a fine, bright, somewhat windy climate, with little or no winter cold, frost, or snow. The windiness is its great drawback, and it is a serious defect.

Catania from the gardens of the Villa Bellini: Mount Etna in the distance.

4.—GIRGENTI.

The mean annual temperature is 17·9° C. (= 64·2° F.). The mean temperature of the coldest month (January) is 9·0° C. (= 48 2° F.); of the hottest month (July), 25·2° C. (= 77·3° F.). The average daily range of temperature is 6·4° C. (= 11·5° F.). The average annual rainfall is 560 mm.

The mean relative humidity is 72 per cent.; the mean maximum temperature is 37·1° C. (= 98·8° F.); the mean minimum temperature is 2·4° C. (= 36·3° F.).

Hosted by Google

The town of Girgenti is at an elevation of from 255 to 400 metres above the sea level, there is a considerable amount of wind, and the air is on the whole fresh and pure except when the sirocco blows. The rainfall is small, and it will be observed that the rainlessness of the summer season is even more marked at Girgenti than at Palermo, also that the rainless season lasts through September at Girgenti, while at Palermo this month shows quite a considerable rainfall.

5.—TERMINI.

(On the north coast, twenty-three miles from Palermo.)

Mean annual temperature (average of twenty years), 18·68° C. (= 65·6° F.); mean minimum temperature, 3·27° C. (= 37·8° F.); mean maximum temperature, 38·15° C. (= 100·7° F.); average annual rainfall, 674·60 mm. = 26·7 in.; average number of days with rain per annum, 85; average number of cloudy days, from 100 to 105.

6.—TAORMINA.

(About midway between Messina and Catania.)

An inspection of the meteorological records kept at the Semaphore station of Taormina proved them to be of considerable interest, but unfortunately they were not in a form admitting of any proper comparison with the returns from the other stations. It would appear, however, that Taormina enjoys a remarkably rainless, bright, and, on the whole, equable winter climate. The temperature at midday at the coldest season is rarely under 10° C. (= 50° F.). The number of rainy days is very low, not more than twenty in the course of the whole winter, according to the officer in charge of the Semaphore station. As observations have only been made for two seasons this figure cannot, of course, be taken as the correct average, but it may fairly be allowed some weight. Snow hardly ever falls. There is much wind, and the north-east wind (greco) is sometimes rather cold. Cold winds from the Etna snowfields are not frequent. The sirocco blows about three or four times per month in the winter season and brings much cloud with it.

Meteorological returns from many other parts of Sicily were available, but probably the above six localities are sufficient to give a general idea of the climate. It will be observed that two of these places are on the north coast—viz., Palermo and Termini; three on the south coast—viz, Syracuse, Catania, and Taormina; and one on the west coast—viz., Girgenti. The materials do not exist for any exact classification of the various types of climate to be found in Sicily, nor is it possible to contrast in any satisfactory way the climates of the coast with those of the higher mountains—e.g., Etna or the Madonian mountains. This must be reserved for the future. For the present it is sufficient to have given the returns from six of the chief stations in the island, noting the broad features of the Sicilian climate and some of the more obvious differences between the meteorology of the six places in question. It is evident that the climate is one of remarkable warmth, mildness, and equability, that winter cold (in the sense in which the inhabitant of northern or western Europe understands the term) is practically unknown, that the proportion of bright sunny days is very high, that the humidity of the air is moderate, that the rainfall varies considerably, but is generally moderate, that cold winds are rare, and that, with the exception of the sirocco, the climate has no grave drawback. Palermo has a larger rainfall and a higher proportion of wet and cloudy days than Girgenti, Catania, Taormina, or Syracuse. On the other hand, the equability of its climate is more marked than that of the other places in question. Catania excels in warmth, brightness, and large proportion of fine days, but is somewhat less equable. Syracuse has a bright climate with a small rainfall, but it is one of the windiest places in Sicily.

In the next article the above meteorological details will be contrasted with those furnished by some of the chief home and foreign sanatoria, and their importance from the point of view of medical climatology will be considered.

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE annual general meeting of this institution was held on the 28th ult., the treasurer, Dr. HOLMAN, being in the chair.

After the election of three pensioners, six foundation scholars, and one Morgan annuitant (the results of which are announced below), the SECRETARY read the report of the Council to the Governors, which was satisfactory in every respect. In this reference was made to an occurrence which was not unprecedented and was likely to happen again—viz., a foundation scholar of marked ability obtained in open examination a scholarship at Cambridge, but could not, from want of means, avail himself of that opportunity of making his way in the world.

In commenting on this "too early souring of a life" the CHAIRMAN laid great stress upon the fact that it was not necessary to capitalise a large sum of money in order to meet such cases, because a sum of, say, £400 or £500 would enable the Council to assist deserving necessitous foundationers for some years; and he read a letter from a general practitioner, who did not wish his name to be made known, offering a cheque for £50 for the purpose in view if nine others would contribute the same amount by a certain date.

The CHAIRMAN stated that the new building for the junior or lower school, capable of accommodating 100 boys, was opened in May, and that the new chancel in the College chapel, designed by Sir A. W. Blomfield and Sons, had increased the accommodation by 120 sittings. The altar was the gift of Mr. John F. France, who had within the last few years so munificiently placed at the disposal of the Council nine free scholarships for girls at the Royal Asylum of St. Anne's Society. During the past twelve months six open university honours in classics, mathematics, or natural science had been won by pupils of the college at Oxford or Cambridge, which was a good result for a school of 250 boys, and should lead to the education given at the college being recognised by the parents of other boys than those being prepared for the medical profession.

The annual report having been duly approved, Dr. Ralph Gooding was elected a vice-president of the college, in consideration of his having collected £1000 as honorary local secretary; after which the usual formal business was transacted. The proceedings were brought to a close by a vote of thanks to the chairman, proposed by Sir Joseph Fayrer, and seconded by Dr. Hare.

The following were the successful candidates at the election:—

Heeley, Margaret M. 8523

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6581 births and 3661 deaths were registered during the week ending June 5th. The annual rate of mortality in these towns, which had been 17·2 and 16·6 per 1000 in the two preceding weeks, rose again last week to 17·4. In London the rate was 15·4 per 1000, while it averaged 18·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·0 in Brighton, 13·1 in Derby and in Birkenhead, 13·4 in Portsmouth, and 13·7 in Norwich; the highest rates were 23·3 in Sheffield, 23·4 in Halifax, 24·9 in Bolton, and 27·1 in Salford. The 3661 deaths in these towns included 364 which were referred to the principal zymotic diseases, against 357 and 355 in the two preceding weeks; of these, 121 resulted from measles, 95 from whooping-cough, 56 from diphtheria, 34 from diarrhœa, 32 from scarlet fever, and 26 from "fever" (principally enteric). No fatal case of any of these diseases was recorded last week either in Swansea or in Derby; in the other towns they caused the lowest death-rates in Croydon, Nottingham, Norwich, and Halifax, and the highest rates in Birkenhead, Burnley, Bolton, and Salford. The greatest mortality from measle occurred in Birmingham, Liverpool, Bolton, Manchester, Salford, and Burnley; and from whooping-cough in Plymouth, Bolton, Manchester, Oldham, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess

Hosted by Google

in any of the large towns. The 56 deaths from diphtheria included 33 in London, 3 in Birmingham, and 3 in Burnley. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 4 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, June 5th, against 14, 13, and 12 at the end of the three preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2601, against numbers increasing from 2380 to 2546 on the five preceding Saturdays; 274 new cases were admitted during the week, against 239, 311, and 278 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 220 and 196 in the two preceding weeks, rose again to 229 last week, but were 49 below the corrected average. The causes of 44, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Nottingham, Hull, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·3 and 21·7 per 1000 in the two preceding weeks, further declined to 20·3 during the week ending June 5th, but exceeded by 3·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·9 in Aberdeen and 17·9 in Dundee to 29·0 in Leith and 37·5 in Perth. The 605 deaths in these towns included 40 which were referred to whooping-cough, 30 to measles, 18 to diarrhœa, 3 to "fever," 2 to scarlet fever, and not one either to small-pox or diphtheria. In all, 93 deaths resulted from these principal zymotic diseases, against 110 and 91 in the two preceding weeks. These 93 deaths were equal to an annual rate of 3·1 per 1000, which was 1·4 per 1000 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 35 and 34 in the two preceding weeks, rose again last week to 40, and included 21 in Glasgow and 14 in Edinburgh. The deaths referred to measles, which had been 49 and 24 in the two preceding weeks rose again last week to 30, of which 15 occurred in Edinburgh, 7 in Leith, and 6 in Glasgow. The 3 deaths referred to different forms of "fever" were within one of the number recorded in the preceding week, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 135 and 128 in the two preceding weeks, further declined to 110 last week, but exceeded by 13 the number in the corresponding week of last year. The causes of 45, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·3 and 28·3 per 1000, in the two preceding weeks, declined again to 25·2 during the week ending June 5th. During the past nine weeks of the current quarter the death-rate in the city has averaged 30·1 per 1000, the rate during the same period being 16·1 in London and 26·3 in Edinburgh. The 169 deaths registered in Dublin during the week under notice showed a decline of 21 from the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 15 in each of the two preceding weeks; of these, 3 resulted from measles, 3 from whooping-cough, 2 from scarlet fever, 2 from diarrhœa, and not one either from small-pox, diphtheria, or "fever." These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·4 in London and 5·9 in Edinburgh. The fatal cases of measles, which had been 5 in each of the two preceding weeks, declined to 3 last week. The deaths referred to whooping-cough, which had been 6 and 2 in the two preceding weeks, rose again to 3 last week. The 2 fatal cases of scarlet fever were within one of the number recorded in the preceding week. The 169 deaths in Dublin last week included 29 of infants under one year of age, and 41 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. Seven inquest cases and 5 deaths from violence were registered; and 72, or more than a third, of the deaths occurred in public institutions. The causes of 9, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during May in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·1 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 8·7, 7·8, and 7·2 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, St. George Hanover-square, Hampstead, Stoke Newington, St. Martin-in-the-Fields, Strand, and St. Olave Southwark; while they showed the largest excess in Chelsea, St. Giles, Holborn, Mile End Old Town, St. George Southwark, Rotherhithe, and Battersea. Ten cases of small-pox were notified in London during May, against 48, 8, and 11 in the three preceding months; of these, 3 belonged to St. James Westminster, 2 to Marylebone, and 1 each to Islington, Shoreditch, St. Olave Southwark, Battersea, and Wandsworth sanitary areas. There were 12 small-pox patients under treatment in the Metropolitan Asylum Hospitals at the end of May, against 43, 17, and 12 at the end of the three preceding months; 9 new cases were admitted during the month, against 8 in each of the two preceding months. The prevalence of scarlet fever in London showed a further increase upon that recorded in recent months; this disease was proportionally most prevalent in Chelsea, St. Giles, Mile End Old Town, St. George Southwark, Newington, Rotherhithe, and Battersea sanitary areas. The Metropolitan Asylum Hospitals contained 2495 scarlet fever patients at the end of May, against 2775, 2468, and 2330 at the end of the three preceding months; the weekly admissions averaged 258, against 228, 208, and 225 in the three preceding months. The prevalence of diphtheria in London showed a slight increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Chelsea, Whitechapel, St. George-in-the-East, Mile End Old Town, St. George Southwark, and Bermondsey. There were 783 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of May, against 855, 776, and 764 at the end of the three preceding months; the weekly admissions averaged 108, against 101 and 127 in the two preceding months. The prevalence of enteric fever in London showed a slight increase upon that recorded in the preceding month; this disease was proportionally most prevalent in Holborn, Shoreditch, St. George Southwark, and Bermondsey sanitary areas. Erysipelas showed the highest proportional prevalence in St. Giles, St. Luke, Bethnal Green, Limehouse, and St. George Southwark sanitary areas. The 20 cases of puerperal fever notified during May included 3 in St. Pancras, 3 in Hackney, and 3 in Rotherhithe sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, May 29th, the deaths of 5105 persons belonging to London were registered, equal to an annual rate of 14·9 per 1000, against 18·5, 17·4, and 16·6 in the three preceding months. The lowest death-rates during May in the various sanitary areas were 9·8 in Hampstead, 11·2 in St. George Hanover-square, 11·3 in Fulham and in Lewisham, 11·6 in Lee, 12·2 in Wandsworth, and 12·4 in Paddington and in Islington; the highest rates were 19·2 in Bermondsey and Rotherhithe, 19·9 in St. George-in-the-East, 20·1 in Newington, 20·9 in St. Saviour Southwark, 23·8 in Limehouse, and 25·7 in Holborn. During the four weeks of May 480 deaths were referred to the principal zymotic diseases in London; of these, 142 resulted from whooping-cough, 136 from diphtheria, 82 from measles, 48 from diarrhœa, 45 from scarlet fever, 25 from enteric fever, 1 from an ill-defined form of continued fever, and 1 from

small-pox. These 480 deaths were equal to an annual rate of 1·4 per 1000. No death from any of these zymotic diseases occurred during May in Strand sanitary area; among the other sanitary areas the lowest zymotic rates were recorded in St. George Hanover-square, Westminster, St. James Westminster, Marylebone, St. Saviour Southwark, and Plumstead; and the highest rates in Stoke Newington, St. Luke, Bethnal Green, St. George-in-the-East, Mile End Old Town, Newington, Bermondsey, and Rotherhithe. The single fatal case of small-pox belonged to Shoreditch sanitary area. The 82 deaths from measles were little more than a fourth of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Bethnal Green, St. George-in-the-East, Rotherhithe, and Greenwich sanitary areas. The 45 fatal cases of scarlet fever were 23 below the corrected average number; the mortality from this disease was highest in St. Giles and Bermondsey sanitary areas. The 136 deaths referred to diphtheria slightly exceeded the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, Stoke Newington, Bethnal Green, Mile End Old Town, Poplar, and Bermondsey. The 142 fatal cases of whooping-cough were 116 below the corrected average number; the mortality from this disease was highest in Clerkenwell, Newington, Bermondsey, and Camberwell sanitary areas. The 25 deaths referred to enteric fever were 8 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 48 fatal cases of diarrhœa were 14 below the corrected average number. In conclusion, it may be stated that the mortality in London during May from these principal zymotic diseases was nearly 46 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 105 per 1000 during May, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Stoke Newington, Holborn, St. Olave Southwark, and Plumstead; and the highest rates in Hammersmith, Clerkenwell, Limehouse, Newington, Bermondsey, and Lee.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAINS G. S. M'LOUGHLIN and J. D. Ferguson have been selected to go with an expedition to East Africa to determine British and Italian spheres of interest.

The under-mentioned Surgeon-Captains to be Surgeon-Majors:—Samuel Hickson, Henry J. Fletcher, Edward Davis, Simpson Powell, Frederick W. C. Jones, James Meek, Arthur E. Morris, Arthur O. FitzGerald, Frederick D. Elderton, Robert E. Molesworth, John W. F. Long, Charles L. Josling, John F. Bateson, William T. Swan, Robert L. R. Macleod, Gofton G. Adams, James M. F. Shine, William B. Day, David R. Hamilton, Robert G. Thompson, Charles T. Blackwell, Robert I. Power, Charles R. Kilkelly, Nicholas C. Ferguson, Samuel R. Wills, Michael L. Hearn, Richard H. Hall, John H. Greenway, Richard G. Hanley, Gerald Cree, Samuel C. Philson, John M. Nicolls, and Frederick W. H. D. Harris.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Lieutenant-Colonel J. S. Wilkins, D.S.O. (Bombay), are placed temporarily at the disposal of the Government of Bombay for employment on plague duty. The services of Surgeon-Captain W. P. Barter, A.M.S., are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on plague duty. The services of Surgeon-Captain W. Westropp White (Bengal), are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on famine duty. The services of Surgeon-Captain F. M. Mangan, A.M.S., are placed temporarily at the disposal of the Government of the Punjab for employment on plague duty. Surgeon-Colonel N. B. Major, A.M.S., is brought on the Administrative Medical Staff of the Army, vice Surgeon-Major-General H. S. Muir, transferred to Egypt. Surgeon-Major J. C. H. Peacocke has delivered over charge of the Karwar Prison.

NAVAL MEDICAL SERVICE.

Staff Surgeon Chas. F. Newland has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. Fleet Surgeon William Henry Stewart, M.B., has been placed on the Retired List, with permission to assume the rank of Deputy-Inspector-General of Hospitals and Fleets. Staff Surgeon J. E. Penn, R.N., recently invalided from the *Philomel*, has been pronounced by the medical board sitting at the Royal Naval Hospital, Stonehouse, to be unfit for further active service.

The following appointments are announced:—Surgeons: P. K. Nix to the *Pembroke;* A. R. H. Skey to the *Alexandra;* John Menary to the *Minerva;* Jonathan Shand to the *Victory;* E. C. Lomas to the *Warspite;* T. A. Penfold to the *Collingwood;* John Andrews to the *Benbow;* Frederick W. Parker to the *Colossus;* C. J. E. Cock to the *Galatea;* and Geo. M'Gregor to the *Excellent.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Robert Thin Craig Robertson, M.B., 2nd Volunteer Battalion the Cameronians (Scottish Rifles), to be Surgeon-Major. Surgeon-Captain H. F. H. Barham, having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve of Officers.

VOLUNTEER CORPS.

Artillery: 1st Lancashire: Surgeon-Lieutenant T. Hammond to be Surgeon-Captain. 6th Lancashire: Surgeon-Lieutenant R. Humphreys, M.B., to be Surgeon-Captain. *Rifle:* 4th Volunteer Battalion the Devonshire Regiment: Frank Bernard Manning gent., to be Surgeon-Lieutenant. 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: John Loftus Cuppaidge, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Royal Scots Fusiliers: William Roxburgh, M.B, to be Surgeon-Lieutenant. 1st Surrey (South London): Surgeon-Lieutenant L. J. G. Carré, M.D., resigns his commission. 1st Volunteer Battalion the Dorsetshire Regiment: Surgeon-Major W. A. E. Hay resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Major W. Mortimer to be Surgeon-Lieutenant-Colonel. 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant J. Brown Robertson, M.B., resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: William Salisbury Sharpe and Frederic Harvey to be Surgeon-Lieutenants. The Woolwich Company: Surgeon-Captain F. L. Stephenson, to be Surgeon-Major.

THE CARE OF THE WOUNDED IN NAVAL WARFARE.

The *Archives de Médecine Navale et Coloniale* for April contain an important article on the care of the wounded on board ship during and subsequently to an engagement. The writer, Dr. Fontorbe, *Médecin en Chef*, who has twice filled the important post of *Médecin d'Escadre*, has embodied his views in the form of a report addressed to his commanding officer, Admiral Gervais, and the latter, in addition to his concluding comment—"Seen: I associate myself with the ideas emitted by Dr. Fontorbe"—has interspersed several approbatory notes in the body of the document. Owing to the transformation which of late years has taken place in naval architecture, as well as to the equally complete transformation which has resulted from the introduction of antisepticism, the notions that formerly prevailed regarding the management and treatment of the wounded in maritime warfare have been entirely revolutionised. For a little while experts differed considerably as to the best way of meeting the altered circumstances, but at the present time there seems to be a consensus of opinion on the point which may be expressed according to the following formula:—1. The wounded during an action constitute an encumbrance which should be removed as quickly as possible. 2. The means resorted to for this purpose should not of themselves constitute an encumbrance greater than that arising from the presence of the wounded men. 3. The employment of combatants for the removal of the wounded is totally inadmissible. Not only would such a procedure tend to create gaps on the line of fire deeper than those produced by the missiles of the enemy, it would also interfere with the supply of ammunition, and prove a source of disorder in several other ways. 4. The removal of the wounded should devolve exclusively upon trained men, who are not

Hosted by Google

otherwise liable to be actively engaged in the action, and should be carried out under the direction of a medical officer, who alone possesses the technical knowledge necessary to prevent a possible aggravation of the injuries *in transitu*. According to existing regulations the duties of the medical staff on board a French man-of-war are thus defined: "During an engagement the principal surgeon and the rest of the medical staff shall remain at the stations that have been assigned to them by the commanding officer." Dr. Fontorbe looks on this ordinance as obsolete, and wishes to substitute an amendment to the following effect: "The medical staff, the hospital (sick-bay) attendants, together with the non-combatants who have been told off in advance for the purpose, are alone permitted to collect and remove the wounded during an action. This duty is to be performed under the supervision and control of the surgeon-in-chief, who receives his authorisation from the commanding officer." Already in certain ironclads these views have been adopted, and it appears that in the German navy an organisation on similar lines has been worked out in detail. The opinion of Admiral Gervais, expressed in a note, is as follows: "I am perfectly convinced that the management of the operations for the removal of the wounded should be entrusted to the medical officer." Dr. Fontorbe next considers the important question of accommodation for the wounded. In some of the war-vessels now afloat not more than twelve wounded men could be suitably accommodated on standing cots within the protected area, while with the exception of the *Redoutable* the maximum number in the most roomy would seem to be twenty-five. Ironclad hospital ships have been suggested, but the idea is premature, if not Utopian. There is, however, a Ministerial order that when a new war-vessel is being designed the provision of suitable accommodation for wounded men shall be taken into account. Meanwhile, every medical officer in charge of a ship should make a study of the various spaces at his disposal, taking counsel with his commanding officer as to the best way of utilising them. There are many equally important matters treated of in this interesting paper, including the transport and treatment of wounded men, the provision and storage of medical and surgical equipment, the necessity for a thorough application from the first of the antiseptic system, &c., but, unfortunately, our overcrowded space does not allow us to deal with them.

ENTERIC FEVER IN THE FRENCH ARMY.

Although, thanks to enlightened sanitation, enteric fever has diminished greatly in the French Army during the last few years, the disease has not yet been completely stamped out, and epidemics of more or less gravity continue to be reported occasionally. On May 3rd the 141st Regiment of the Line was ordered from Marseilles to Carpiagne to go through a course of musketry practice. While quartered at the insalubrious seaport the corps had suffered to a slight extent from typhoid fever, but shortly after its arrival at the ranges, where the men had to live under canvas, the affection assumed a more serious form, and it was reported that upwards of a hundred cases had occurred. Dr. Dujardin-Beaumetz, Inspector-General of the Health Department, was sent to inquire into the origin of the outbreak, and apparently the barracks of Saint Charles at Marseilles are at fault, for disinfecting operations on an extensive scale have been undertaken in them. The remainder of the troops at Carpiagne, numbering in all about 3000 men, are apparently in good health; and yet there are not wanting critics who seek to ascribe the fever to military *surmenage* and the hardship of camp life. During his inspection, which was most exhaustive, Dr. Dujardin-Beaumetz was accompanied by Surgeon-Major Dziewonski; and the record adds that all the recommendations that were made with a view to the rooting-out of the evil were immediately given effect to by General Canonge, "who is himself a distinguished member of the medical profession."

THE ALLEGED UNSATISFACTORY STATE OF THE MILITARY FORCES.

The Service Members' Committee of the House of Commons have addressed a letter to the Prime Minister calling the Marquis of Salisbury's attention to the very unsatisfactory condition of the military forces at the present time, and pointing out that the Forces on the home establishment, more especially those of the Line and Horse and Field Artillery, are inadequate to meet the requirements. The linked battalion system does not seem to have answered the expectations formed of it by its advocates. The recruiting question is an old difficulty, liable to fluctuations from time to time; but it is becoming more and more obvious that the supply of army recruits is inadequate. The remedy is not easy to find, but with a voluntary system of recruiting it means that additional inducements to enlist must be held out, and that the pay of the soldier will have to be increased. The Treasury is not likely to give its assent to this unless it is obliged to do so; but the step will, we presume, have to be taken sooner or later.

ARMY TEMPERANCE WORK IN INDIA.

The Army Temperance Association is successfully carrying on its good work in India. A meeting of the association was recently held at Simla, at which the Viceroy of India, the Commander-in-Chief, and other officials spoke. Sir George White gave some interesting details. The number of members of the association was 22,810 last year. Touching on court-martials, His Excellency said that while 4·70 per 1000 represented the number of convictions amongst abstainers, those among non-abstainers amounted to 42·27 per 1000; and the figures just received from the Principal Medical Officer of H.M.'s forces in India showed that last year only fourteen cases of delirium tremens had been admitted into hospital, whereas if the army in India had been of the same strength as at present the admissions would have been 481. Sir George White also alluded to the military and fighting qualities of the Turkish soldiers, who were water-drinkers.

THE ALDERSHOT SEWAGE FARM.

We notice that this old question is again to the fore. Our service contemporary, the *Army and Navy Gazette*, of the 5th inst. states that it is a never-ending subject, and that it is difficult to know how it will be ultimately settled. The present sewage farm has been condemned long ago, as everybody knows; and notwithstanding that some improvement has taken place under a new system of management the fact remains exactly where it was—viz., that a new sewage farm on a new site is absolutely necessary, and the sooner this is carried into effect the better.

MOVEMENT OF TROOPS IN THE COLD WEATHER IN INDIA.

According to the Indian papers the movement of the troops in India during the next cold weather will be on an extended scale. Many of them will be on the march for some time, and the marches will be through districts at a distance from the large cantonment stations. Troops are usually very healthy under such circumstances during the cold season in India if proper sanitary precautions be taken, and it is thought desirable that British soldiers should occasionally be more *en evidence* than they are in remote districts of India.

THE WHITE CROSS LEAGUE.

We have received a copy of a resolution of the Council of this society which has received the approval of the Archbishop of Canterbury, the president. The resolution respectfully calls upon the archbishops and bishops to confer with the senior authorities in the Royal Navy and Army with a view to making it generally known that fornication is a deadly sin and an evil highly prejudicial to Her Majesty's services.

SUBATHU.

It will be recollected that there has recently been an outbreak of enteric fever among the troops at Subathu, and that this hill-station has not had a good medical history in the past. The Government of India have sanctioned a project for the provision of a pipe water-supply for the cantonment, and an officer of the Royal Engineers has been deputed to prepare a detailed estimate of the cost of the work.

THE MEDICAL SERVICES IN INDIA.

The plague and famine in India have required the presence of a large number of medical officers, and the Government of India has consequently been compelled to restrict the number of medical officers going on privilege leave.

THE HEALTH OF THE TROOPS IN INDIA.

The despatch of the Government of India on the contagious diseases question is understood to have been transmitted home by the incoming mail.

Sir H. S. Cunningham's rejoinder to the reply of Mr. Henry J. Wilson, M.P., to the former gentleman's charge that he (Mr. Wilson), in his pamphlet "A Sanitary Failure," had garbled quotations from Blue-books, has been published in leaflet form. Mr. Wilson boldly asked for proofs of Sir H. S. Cunningham's accusations, and these proofs are here given. In one part of the letter he purports to show that Mr.

Hosted by Google

Wilson has been guilty of suppressing a passage which reveals the fact that the Army Sanitary Commission has throughout concurred with the Government of India in insisting on the necessity of protective measures.

Correspondence.

"Audi alteram partem."

"SECONDARY RASHES IN SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 29th is an editorial notice of an article by Dr. J. O. Symes in which he attributes the nephritis, dermatitis, and other inflammatory changes of certain specific fevers to the elimination of the virus from the body. Perhaps I may be allowed to point out that in 1890 I advanced the theory that such organic lesions of skin, kidney, alimentary and respiratory tracts, and so on, were due to the excretion of an irritant from the blood. Further, I traced the analogy between specific bacteria (and their products), certain drugs, and such chemical tissue irritants as that of gout. The facts are published in a small book on Excretory Irritation lately issued.

I remain, Sirs, yours faithfully,

Temple, E.C., June 2nd, 1897. DAVID WALSH, M.D. Edin.

"URIC ACID IN THE BLOOD."

To the Editors of THE LANCET.

SIRS,—Dr. A. P. Luff has informed your readers[1] of the extreme delicacy of the murexide test. Nevertheless, there is an exact procedure necessary to secure infallible evidence of small quantities. For example, one large drop of solution of potassium urate containing 0·4 per 1000 of uric acid—i.e., about a thirtieth of a milligramme of uric acid—gives me one success and three failures, and yet my general procedure has been the same. So that if these experiments were applied to four different solutions I might have concluded uric acid to be absent in three of the solutions. "The Physiology of the Invertebrates," by A. B. Griffiths, contains a demonstrable history of uric acid in our fauna from the protozoa to the mollusca, yet this excellent work does not give us the exact data whereby we may obtain the infallible evidence so necessary to be had. One grain of ammonium chloride added to twenty minims of an alkaline solution of urate immediately precipitates the uric acid, except 1 per 28,000; five minims solution (1—4) of ammonium chloride also determines rapid deposition of urates in about half an hour. Applied to the blood I thought I could obtain morphological evidence of urates in the blood corpuscles by means of this alkaline ammonium chloride test. In the absence of uric acid from normal blood, as demonstrated by Dr. Luff, I would ask, What are these coloured microcytic or albocytic granules about a micro-millimetre in size obtained by this test used with a drop of blood from a pricked finger? In the "Manual of Pathological Anatomy" of Cornil and Ranvier, page 81 (translation), it is stated that "everywhere the deposit is primarily made in the cells." Again: "The primary appearance of uratic infiltration in the cells proves that the latter play an active part even in the phenomena of simple deposit, and differentiates this process from that of calcification, in which infiltration commences primarily in the ground substance." It has appeared to me that ammonia may be a factor in the commencement of urate deposition. Perhaps Dr. Luff will be good enough to formulate an exact procedure for the murexide test for workers.

I am, Sirs, yours faithfully,

JOHN BARKER SMITH, L.R.C.P. Lond.

Holmdene avenue, Herne Hill, S.E., May 25th, 1897.

"THE EXAMINATIONS FOR DENTISTS."

To the Editors of THE LANCET.

SIRS,—In the report of the proceedings of the General Medical Council on May 29th, which appears in THE LANCET of June 5th, I notice that Mr. Thomson objected to dental students being questioned on parotid fistula, tongue-tie and its treatment, removal of the tongue, sebaceous cyst of the scalp, dermoid cyst, wound of the radial artery, gummata, and the stages of syphilis, and their treatment. Mr. Bryant, as representative of the Royal College of Surgeons of England, was asked whether he thought this an examination suitable for gentlemen who were seeking a qualification as dentists pure and simple, and he said that he would put the matter before the College. May I say, as a dentist and a teacher, that I should be sorry to see the subjects mentioned struck out of the examination? I should be very sorry to see dental surgeons trespassing on the domain of surgery, but dental students ought to be taught everything that may be of use to them in their daily work, and although the questions objected to may at first sight seem beyond the province of a dentist I think a good deal could be said in their favour. As regards parotid fistula, which is first on the list, one must remember that sinuses arising from diseased teeth, especially from wisdom teeth, are far from uncommon in the parotid region; and in the dental operation for the removal of impacted wisdom teeth the slip of an elevator, or the external pointing of a large abscess, may be followed by a salivary fistula, so it is just as well that a dental surgeon should know that there is such a thing as a salivary fistula in order that he might refer the case to a surgeon for treatment. With the same object in view I think it desirable that a dental surgeon should know anything that would help him to diagnose a dental or dentigerous cyst from any other kind of cyst, whether dermoid or sebaceous. It will do the dental surgeon no harm to know the difference between a tongue-tie and the adhesions between the mucous membrane of the lip and gum which not infrequently occur in the incisive region as the sequel of ulceration set up by denuded roots of teeth in children. Dental surgeons should also be well versed in all the means available for the arrest of hæmorrhage, and I think that a candidate who knows how to deal with the various forms of hæmorrhage that occur in the mouth might as readily apply the principles of arresting arterial hæmorrhage to the radial artery as to the facial. Be this as it may, I think it very desirable that particular attention should be given to syphilis in its various stages and its treatment. Primary chancre of the lip is uncommon, but the dental surgeon should recognise it, not only for his own sake, but for the protection of other patients whom he may be treating. Specific lesions of the secondary stage are often seen in the mouth, and as for tertiary syphilis dental surgeons are often required to restore artificially the destruction of the hard and soft palate that follows gummata and necrosis. Hereditary syphilis modifies the form of certain teeth, affects their arrangement, structure, and liability to caries. It is needless to refer to the connexion between inherited syphilis and cleft palate, or to add that much can be done by the dental surgeon in the treatment of cleft palate by artificial means.

Mr. Thomson objects to dental students being examined on removal of the tongue, but one should recollect that a large number of the operations required are for removal of epithelioma arising in the first instance from the irritation caused by a decayed tooth. The greater the knowledge of the dental surgeon about epithelioma and its treatment the smaller will be the number of tongues that require removal, and the more the dentist knows about the difficulties of the operation the less likely will he be to attempt it. There are other reasons for not restricting the examination questions to the teeth and their immediate surroundings, for, regarding the profession of dental surgery as a whole, we find that every year shows an improvement in the educational standard. Qualified men are taking the place of unqualified men, and many of us look forward to the time when the dental diploma will be taken after a registrable medical qualification, and then, indeed, will dental surgery be acknowledged a true specialty of surgery. I am, Sirs, yours faithfully,

F. NEWLAND-PEDLEY, F.R.C.S. & L.D.S. Eng.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—I had not intended to reply further to Dr. Bastian, but Dr. Harry Campbell renders it necessary. In his last letter[1] Dr. Bastian said "The *acquirement* of language is a

[1] THE LANCET, May 22nd, 1897.

Hosted by Google

twofold process, comprising what is termed a receptive and an expressive side" (the italics are mine. If language *is* acquired does it matter whether or not it is a twofold process. I stated that it was acquired, and Dr. Bastian disputed it). Once again let me beg your readers to think in concrete, not in abstract terms; let us take the case of a particular word. It appears, then, if I understand my censor right, that an English child learns—i.e., acquires—the word "picture" for instance, but does not learn to *say* it. The distinction is fine but, if Dr. Bastian is right, important. This sound, like all others, is produced by the very nice and complex coördination of a large number of muscles. In other languages the same object is indicated by totally different sounds, each requiring a different coördination of the muscles. Are we to understand then that, apart from all experience, from all tentative efforts, from all *learning*, the English child is able to make this particular coördination. But the word "picture" is not comprised in the French language, and therefore the power of making this particular coördination of muscles cannot arise apart from experience in the French child; it must, of course, be acquired by him. Nevertheless, the French child, reared in England, speaks it with as much facility as the English child, and, if he subsequently learns his native language, speaks that with an English accent. Does not this prove that language is acquired in its expressive as well as its receptive side—i.e., that the power of making quickly and easily all those separate delicate muscular coördinations by means of which the many words of a language are expressed is acquired—just as the power of making quickly and easily all those separate delicate coördinations by means of which we are enabled to write is acquired? If, as Dr. Bastian maintains, speech is a "deferred primary automatic movement," why does the French child reared in England subsequently speak French with an English accent? Dr. Bastian rests his case on two or three children who apparently began to speak by uttering certain words with singular distinctness. But had these children before then been absolutely dumb? Had they never before attempted to coördinate their speech mucles by uttering the usual babbling and inarticulate sounds that infants make, and which, in the ordinary child, may be observed to grow in distinctness with practice till at length the child speaks clearly? The case of bi-pedal progression is exactly the same as that of speech. The infant manifestly cannot coördinate its muscles of locomotion at birth, and, as I think, very plainly learns to do so. In the case of Sir R. Quain's daughter, was she never allowed to use her legs, and so acquire precision of movement? Was she never allowed to crawl about, for instance? Was she never placed on her feet? The muscles of the upper extremity are much less powerful and adapted for locomotion than those of the lower, yet an exceptional man, who had otherwise developed and learned to coördinate them, might at the very first attempt walk on his hands. Thus also might an exceptional child walk at the first attempt on her feet.

Next, as to Dr. Harry Campbell. Low in the animal scale an animal develops fully, mentally and physically, in the absence of all stimulation other than that of sufficient food. In other words, it is a product of heredity pure and simple; exercise and use is not necessary to the development of its mind and body. Thus we see the caterpillar metamorphosed into the butterfly while hanging quiescent; thus even so high in the scale as the frog, if a tadpole finds its way through a crevice into a small cavity, it will there, if it obtains sufficient food, though it leads a purely vegetative life, develop into a normal frog. But as we ascend in the animal scale we find that this power of developing in the absence of stimulation (of exercise, of use) is gradually lapsed, and replaced by a power (which does not exist low in the scale) of developing in response to stimulation. Compare, for instance, a dragon fly at one end of the scale and man at the other. Physically a dragon fly, in the absence of stimulation, undergoes extraordinary metamorphoses; mentally it can *instinctively* coördinate all its muscles, and has besides many other wonderful instincts, but so far as we know it does not change physically in response to stimulation; mentally it learns and remembers nothing. Even to an animal so high in the scale as a fish has memory been denied,[2] and of course all that lies within the memory is acquired. Far different is the case of man. He is born helpless; his physical structures "immature," his mind a blank; but subsequently in response to stimulation (use, exercise, experience), he develops enormously both mentally and physically. On consideration it will be seen that nearly all that separates the adult man from the infant is acquired (i.e., has resulted as a response to stimulation, has resulted from exercise and use). For instance, if the joints of an infant's limb—e.g., the arm—be locked, as by disease, so that the limb cannot be used, it does not develop. Again if a man—e.g., a blacksmith—uses his muscles beyond the ordinary he gets an extra development of them, and this additional development is said by biologists to be acquired. But, as we see, the "normal" standard of development is attained as a response to stimulation, similar in kind but less in amount, whence it is plain that the normal degree of development is also acquired. Mentally, as I say, the infant's mind is practically a blank. It can instinctively coördinate only a few groups of muscles—e.g., those of breathing, sucking, defæcating, &c.—and in these the coördination is never very delicate. How different is the mind of the adult man with its wonderful power of delicately coördinating the different groups of muscles, and with the vast contents of its memory, and all that arises out of memory.

Surely then I am right in saying that the faculties of language and bi-pedal progression are both acquired. Dr. Harry Campbell says that the majority of physiologists think otherwise. But this is not a question of counting heads but of facts, and the discoverer of a fact is always at first in a minority of one.—I am, Sirs, yours faithfully,

Southsea, June 1st. G. ARCHDALL REID.

[2] THE LANCET, Jan. 23rd, 1897, p. 257.

THE GENERAL MEDICAL COUNCIL AND MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—When the subject of Medical Aid Associations came up for discussion at the May session of the General Medical Council I tried to show that if the Council took action it must attack those practitioners connected with hospitals at which medical aid was given as those practitioners who act as officers to medical aids. To establish this statement I referred to the gross and sad state of affairs at Guy's Hospital where a patient by paying 3*d*. per week or 6*d*. per fortnight (not 6*d*. per visit be it noted) can obtain, as an out-patient, medical or surgical treatment and medicines. This "charity"—if the payors will permit the use of this word—appoints four assistant surgeons and four assistant physicians and pays such practitioners £100 per annum each. During the year ending March 31st, 1895, the out-patients paid £928 and the in-patients £3965. As this seems a fair commercial speculation—because I fail to see how it could *honestly* be called *charity*—I asked, How many out-patients were *refused* treatment? As was to be expected, no answer could be given. Threepenny-a-week patients represent income, and income must be maintained. Hence the present "fifteen per cent. charity" hospital business which is now degrading our charities. Then look at the result of this demoralising system. A young practitioner wishing to live and to compete with the practitioners of Guy's "cuts" their price and charges, not threepence, but one penny per week. Thus we have the various medical aids and their baneful accompaniments. Go a step further down, and we have the private practitioner trying to "cut" the charity prices of Guy's and of the Medical Aids. He charges threepence and sixpence *per visit*, not per week. He is sneered by the chief sinners, who all the time use the charity to kill off competitors. My advice to each practitioner is—Have nothing to do with clubs, medical aids, or sixpenny fees, and above all shun, as one should shun evil, all penny and threepenny a week hospitals.

Mr. Bryant stated at the Council meeting that Guy's was his hospital and that he "must repudiate in the strongest words he could use the accusations which had just been made against it. Dr. Rentoul was entirely in the wrong, and if he would take five minutes' trouble ..... he would probably come back next session and apologise for bringing forward such a false accusation." This is strong language for Mr. Bryant. He suggests I should bring forward documents in proof. I gladly do so. May I refer him to the "Annual Report of Guy's Hospital" for 1895, and will he ask the superintendent of Guy's to show him a copy of a letter dated

Hosted by Google

Oct. 16th, 1896, which the superintendent kindly sent to me on this very question?

My stay upon the Medical Council may be long or it may be short. But if Mr. Bryant thinks for one moment that I deliberately concoct statements to wilfully mislead the Medical Council or that I am going to accept his suggestion of "apologising" to the Council because I have been "guilty" of making a statement true in word and fact, then all I can say is that he has not taken my measure with accuracy.

If Mr. Bryant will refer to page 2 of the above annual report he will find that not only are *out*-patients treated for threepence per week, but that in-patients are treated for from 1 to 3 guineas per week. Practitioners would be also edified if, in his reply, he would state the maximum and minimum fees charged by the Practitioners connected with Guy's *in* pay patients, above or exclusive of the 1 or 3 guineas per week. If he will further refer to the Report of the House of Lords on "Metropolitan hospitals," 1892, p. 10, he will find further documentary reference to the sales of charity at Guy's.

Awaiting his reply,

I am, yours obediently,

ROBERT R. RENTOUL.

THE NEED OF ORGANISATION IN THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—I have received a pamphlet entitled "The Just Claims of the Provident Dispensary System" by the secretary of the Provident Medical Association,[1] and have no doubt but that most other London medical men have had copies sent to them. The pamphlet emphasises strongly the necessity for organisation amongst medical men, and as this formed the subject of a paper I had the honour of reading before the Hunterian Society in 1895[2] I venture to send you a few observations on the pamphlet in question. In many of his remarks, as contained in the pamphlet in question, I agree very cordially with the writer, but I disagree with him *in toto* as to the result he arrives at in respect to the fees to be received by medical men attached to provident dispensaries—one of the crucial points.

I must premise that I am able to state on the strength of the observations of a patient of mine—observations covering fifty years' work in a leading builder's office—that wages have increased within the period I have mentioned some 80 per cent., that about 80 per cent. less work is done, and that the work on the whole is inferior to what it used to be, and that, as we all know, there is a marked tendency amongst this class in the direction of undervaluing (from a monetary point of view) the services of medical men.

It is fairly certain that the expenses of living have not increased in the same proportion as wages. Per contra, a medical man cannot, I think, live on less than £400 per annum, with an additional £200 for his trap. If he be properly paid his income, therefore, should amount to at least £600 per annum. The author of the pamphlet evidently considers that "between 4½*d*. and 6*d*. per attendance, whether at the dispensary, the doctor's surgery, or at the patient's house," is a fair remuneration. In order to earn an income of £600 24,000 patients per annum would have to be seen, or at the rate of about 66 per diem all the year round at 6*d*. each. If he does confinements the additional income so earned will probably allow him to have his Sundays free, but would not pay for holidays. In order to be able to earn this, starting at a far less income at age twenty-three or so, he has to lay down capital and to devote five years to acquiring his professional knowledge.

Does it not emphasise the necessity for organisation amongst us when we are assured by one who ought to know about it that such are the conditions under which we should expect to live? The reasons adduced are want of medical union and competition with "charitable" organisations, and not because we know less than we did or do our work less satisfactorily.

Into the fallacies respecting the declarations made by candidates for membership respecting their incomes, the amount of responsibility attaching itself to medical officers of provident dispensaries as to the admission of well-to-do persons into the dispensary—in respect to both of which I think he takes a totally wrong view—I will not enter. I feel that the challenge thrown down should not be allowed to remain unanswered, especially since the author states that "the interests of the general medical practitioner have been placed (in the 'Battle of Clubs') somewhat in opposition to the various means by which medical advice is being obtained." It would appear that it is time they were.

I am, Sirs, yours faithfully,

ROWLAND HUMPHREYS.

Fellows-road, South Hampstead, N.W., June 7th, 1897.

[1] A paper read at a special meeting of the Council of the Charity Organisation Society on Jan. 4th, 1897.

[2] Medical Magazine, June, 1895.

THE SUPPLY OF TETANUS ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—I notice with some interest a case of traumatic tetanus treated successfully by antitoxin reported in THE LANCET of June 5th by Dr. Chalmers. Curiously enough, this case and a similar one, of which the notes were published in THE LANCET of April 10th, 1897, occurred in June of last year. In sending up those notes I drew attention to the difficulty of obtaining a supply of antitoxin, and Dr. Chalmers has further emphasised this fact. I wish to point out that so long as the only places at which the antitoxins can be obtained are either Messrs. Allen and Hanburys, Messrs. Burroughs and Wellcome, or other chemists in London, if the want arises on a Saturday after those firms have closed their places of business a delay of forty-eight hours is at present unavoidable. That forty-eight hours may mean a matter of life and death in some cases is indisputable. Surely it is time that a supply of the various antitoxins should be kept by the Public Health Departments in the various large towns throughout the kingdom, so that when required they should be easily obtainable at short notice.

I am, Sirs, yours faithfully,

Brighton, June 7th, 1897. ARTHUR H. BUCK, F.R.C.S.

MESCAL INTOXICATION.

To the Editors of THE LANCET.

SIRS,—In my note on the above subject in THE LANCET of June 5th I neglected to mention that I obtained the buttons through Messrs. Potter and Clarke, 60, Artillery-lane, E., who are able to supply them in small quantities.

I am, Sirs, yours truly,

HAVELOCK ELLIS.

Carbis Water, Lelant, Cornwall, June 9th, 1896.

THE DIAMOND JUBILEE.

To the Editors of THE LANCET.

SIRS,—Your suggestion regarding the publication of an official programme of the proceedings on the 22nd inst., by which all, even the poorest, of Her Majesty's subjects witnessing the spectacle should be able to identify the various bodies—the troops, colonial corps, and detachments—representing the colonies and dependencies of the British Empire, strikes me as a very wise and excellent idea. The occasion is altogether unique, and the opportunity should not be lost for enabling everybody to realise the geographical extent of the various territories within the sphere of British influence and under the British flag. It would obviously add immensely to the interest of the occasion if those taking part in the procession could be readily identified by the crowds of spectators as the panorama of living pictures passed along. What is wanted is that the power and responsibility of this country, the interdependence of Great and Greater Britain, and all that this implies in the way of the ties—social, commercial, and sympathetic—uniting them with one another, of which the Queen, as the head of the Empire, is the symbol, emblem, and token, should be brought home and impressed upon the imagination of the people. The official guide should be of small and handy size so that its pages could be easily turned over and referred to, and it might also be sufficiently illustrated to fulfil its purpose. It should not cost more than a penny or a halfpenny. It would sell in thousands—possibly millions—and realise a large profit, and the surplus, after the payment

Hosted by Google

of all expenses, would make a handsome addition to the Prince of Wales's Hospital Fund.

I am, Sirs, yours faithfully,

June 7th, 1897. VIATOR.

*** Our correspondent will see that our suggestion has been adopted by the Prince of Wales's Hospital Fund, so that the proceeds will go in the direction in which he thinks they should go.—ED. L.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

COVENTRY.

History of the Coventry Provident Dispensary.—Action of the Medical Profession against this Institution from 1829 up to the Present Day.—Formation by the Medical Union of a Public Medical Service.

IN 1889, when public opinion at Coventry was much exercised by the question of hospital management and the claim of the working men subscribers for a share of representation as governors of the Coventry and Warwickshire Hospital, the Coventry Provident Dispensary also came in for a large measure of criticism. At a conference held that year to discuss the administration of the Poor-law, Mr. F. Townsend, Member of Parliament for Stratford-on-Avon, delivered a speech expatiating on the advantage of provident dispensaries as inculcating habits of thrift, tending to reduce the poor rates, and as most beneficial generally to both workmen and medical men. The storm seems to have found its origin in this attempt to prove too much. Mr. Stanton, formerly Mayor of Warwick, who had presided at the previous annual meeting of the Coventry Dispensary, does not appear to have been very favourably impressed with the experience he then gained, for he argued against the optimist view taken by Mr. Townsend, M.P. Mr. Stanton urged, on the contrary, that at Coventry there were members of the dispensary "who rode in their carriages, and that the medical officers had a great objection to attending such members. At Warwick no one was admitted who earned 30s. a week. and at Leamington the line was drawn at 40s." These speeches, reported in the local press, gave rise to a controversy, and the arguments for and against such dispensaries, with which we are now familiar, were brought forward. It was pointed out that there were about 20,000 members of the Coventry Dispensary and only five medical men. These medical men, considering their many other duties, could not attend properly to the health of such a vast population. At the price paid their services were charitable services, and it would not be possible that so many persons in the town were in need of charity. To prevent the abuse by the rich of institutions meant for the poor many proposals were made. Among others it was suggested that a list of all members of the dispensary should be printed and deposited at the Free Library, and the public invited to look over the list, so as to denounce all those who were too rich to belong to such an institution. Then the names of all candidates for membership should for the same purpose be hung up outside the dispensary for a month. At a meeting of the Warwick Board of Guardians the Coventry Dispensary was mentioned, and, according to the *Coventry Standard* of June 22nd, 1889, Mr. Longe, Local Goverment Board Inspector, inquired: "Do you mean to tell me that half the population of Coventry are tied down to have their medical attendance from these four or five doctors?" And on receiving a reply in the affirmative he exclaimed: "What a monopoly!"

These attacks on the dispensary did not, however, check the growth of that institution. At the annual meeting held in the spring of 1890 the secretary was able to report an increase in the number of members, amounting to 1462 for the year, and this brought up the total membership to 21,010. Lord Leigh, who presided, explained that the Coventry Institute was the third provident dispensary founded in England, the first being at Southam and the second at Northampton, and urged that such institutions materially helped to prevent pauperism. The next annual meeting was held in April, 1892, and then, according to the *Coventry Standard* of the 30th of that month, the chairman, Mr. J. Bill, said that "it was difficult to give the exact membership, but approximately it was about 25,000 or 26,000." The medical officers' reports showed that during the year 21,305 cases of illness were entered, but as cases are often entered more than once this probably did not represent more than some 10,000 persons relieved. Their drug bill had amounted to £519 8*s.* 9*d.* When to these remarkable figures we add that there were also numerous medical aid societies organised by life insurance companies and various benefit clubs and medical men's private clubs, it will be seen that little remained for private practice. Though there were not many medical men practising at Coventry the incomes they earned were small and quite out of proportion to the population of the town. The figures given by the dispensary proved that matters were getting from bad to worse, and it was under the stress of these distressful circumstances that it was at last determined to summon a meeting of the profession and see what could be done.

This meeting was held on Dec. 10th, 1892, and of the twenty medical men then in practice at Coventry sixteen were present, including some of the staff of the Coventry Dispensary. The meeting had been convoked to discuss the question of imposing a wage limit in connexion with contract work for certain clubs. Dr. Phillips spoke, urging that the members of the profession should consider themselves as a body of men working for a common end—namely, to benefit their fellow men and to receive a just remuneration for their labour. This latter end in any case was not realised, for at least from £7000 to £8000 per annum were withheld from the medical profession. Dr. Phillips pointed out that though the population of Coventry only amounted to 52,000, some 26,000 of this number were said to belong to the Coventry Dispensary. Some 13,000 others belonged to various clubs, and there were about 3000 hospital patients, making a total of 42,000 out of a population of 52,000 who were not paying any medical man. The profession rather than the general public was responsible for this state of affairs. It was obvious that the public would take advantage of the cheapest market. The dispensary medical officers had been paid the previous year £1723 4*s.* 5*d.* for attending to 26,000 persons, and this meant 1*s.* 4*d.* per annum, or $\frac{4}{13}$th of a penny per week, per member. Had these dispensary medical officers received a penny per week per member they would have shared between them £5600 instead of £1723. Then when a consultation was required a member of the dispensary could obtain a second opinion from any of the other medical men on the staff without paying a consultant's fee. To remedy this deplorable state of affairs Dr. Phillips thought that either a wage limit must be established or the profession must take the whole matter in their own hands and organise a public medical service entirely managed by themselves. After some other speeches the meeting carried a resolution to the effect that a wage limit should be imposed. It was also resolved that a deputation should wait on the managing committee of the dispensary to bring the matter of a wage limit before them, and the three medical men belonging to the dispensary staff who were present promised to support the deputation. This promise apparently was not fulfilled and a serious dispute ensued.

The dispensary medical men now withdrew from the movement which the other members of the profession were carrying forward. Many more complaints against the dispensary were made. The subscription was denounced as too low. This was fixed at a penny per week for all persons above twelve years of age, and a halfpenny for children under that age, "except in a family consisting of not more than three children, when a penny per week, and in a family of more than three children twopence per week shall be considered sufficient for all children under twelve years of age." Thus three children could be insured against sickness for a penny and an unlimited number of children for twopence. The argument was that children gave more trouble than adults, and that therefore the subscription for each child should be the same as that for adults. But even the adults do not all pay a penny a week. The dispensary will take any club at 3*s.* per annum per member. Private clubs given up by medical men were taken by the dispensary at this low figure, and several medical men had private clubs. An incident of this description occurred a few weeks ago. Dr. Phillips gave up the "Briton's Pride," a branch of the Oddfellows' Society. They went to several of the

[1] A reprint of the previous articles on the above subject has been published in book form entitled "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1*s.*

Hosted by Google

medical men belonging to the reform party, who all refused to take the club for less than 3*s.* 6*d.*, but the dispensary gladly took the club for 3*s.* Then, again, the rule is that no member of the dispensary can claim medical benefits before he has been three months on the books, but rule No. 23 says :—

"No one actually labouring under sickness can be admitted a member unless two healthy persons above twelve years old enter at the same time, and each pay one year's subscription in advance. Any such person unable to procure two other persons to enter with him shall, by paying 10*s.*, be entitled to the benefits of the institution for three months, and afterwards continue a member by paying the usual rate of subscription."

Practically this means that the medical men are, by their services, to pay a commission to those sick persons who join when sick and are able to recruit two new members. Why should the medical men be the only persons to pay this commission? All this gives a commercial and unprofessional colouring to the institution which is naturally obnoxious to the profession. Finally, the fact that the dispensary medical men agreed to meet each other in consultation and not to call in any other Coventry practitioner was considered very objectionable.

The deputation which waited on the committee of the dispensary and spoke on behalf of the general meeting of the Coventry practitioners, having totally failed in its purpose, another general meeting of the profession was convoked on Jan. 24th, 1893, and it was then decided to establish a public medical service. This was an important departure, and the rules of the new body merit a detailed examination. They were drawn up finally on April 10th, 1893, when the following resolution was unanimously adopted by the eleven medical practitioners present—namely, that the object of the public medical service should be :—

"To provide efficient medical attendance at a small weekly payment for members of families resident in Coventry and Stoke whose average annual income does not exceed £2 per week."

The principle of admission for members of the profession is based on the desire to prevent anything like a monopoly arising. All fully qualified practitioners are admitted to membership. The only exception is given in Rule 10, in the following words :—

"That any member of the medical profession commencing practice in Coventry without an introduction shall not be eligible for election to the service during his first year of residence in the city."

The committee of management consists of all the medical staff of the service, which meets quarterly, and oftener when necessary. A sub-committee of at least three members, elected at each quarterly meeting, attends to all current business. Rule 7 is very important, for it deals with a difficult question. It states :—

"That a number of chemists be invited to coöperate by dispensing the prescriptions of the service, and that payment at the rate of not more than 1*s.* per annum be allowed for each patient on the chemists' lists."

The word "patient" is, I think, a mistake; the word member should have been employed. By this means the dispensing chemists, who are all naturally much opposed to the Coventry Provident Dispensary, have been won over to the Coventry Public Medical Service and readily accepted these terms. There are twelve dispensing chemists on the list of the Public Medical Service, and each subscriber selects the chemist he prefers. The subscriber or member likewise selects the one he prefers out of a list of ten medical men, and he can go to the private surgery of the medical attendant between 9 and 10.30 A.M. or 6 and 7 P.M. Of course, if the patient is not well enough to go out his medical attendant will visit him at his own house if a message to that effect is sent before 10 in the morning. This system scatters the patients among the different druggists' shops and the different surgeries, instead of crowding them together in one waiting room as at the dispensary. It is more convenient to the medical men, who are thus enabled to stop at home; it is more advantageous to the dispensing chemists, who do not lose the custom of the members; and it avoids the risk of infection which the crowding together of all the patients in the single room of a dispensary must occasion. The terms of membership are a penny per week per member, whether the member be an adult or a child. Members over sixty years of age must pay an entrance fee of 5*s.*, and patients who are ill at the time of entrance must pay an entrance fee of 10*s.* 6*d.* to the medical officer in charge of the case. Female patients are not entitled to benefit during confinement or for diseases arising therefrom. Attendance at confinement can be arranged for privately, and patients suffering from diseases arising from intemperance or immorality are not eligible for the benefits of the service. A collector was appointed at a salary of £1 a week and a 10 per cent. commission on all collections exceeding £6 10*s.* per week. Every medical officer had to give £2 on joining the service, and render himself liable for £3 more, if required. Finally, and so as to exercise a control in respect to medical ethics, Rule 14 states :—

"That the Committee of Management shall have power, by a two-thirds' majority, to expel from the service any member who, they may consider, has been guilty of infamous practice in a professional sense."

The definite formation of this public medical service was greatly stimulated by the issue of a handbill, which clearly showed how impossible it was to hope for effective reform of the Coventry Provident Dispensary. As typical of the spirit animating the committee of that institution, the handbill is worth quoting. It reads as follows :—

"Important Notice.—To all those connected with the Coventry Dispensary.—Owing to the splendid success of the institution certain outside medical men are trying to coerce the Dispensary Committee to fix a wage limit for membership, and raise the rate of pay for children. The impracticability of the first is self-evident, while the latter would inflict great hardship on those who have to support large families. While every office is adequately paid and there is a large balance in hand it is undesirable and unnecessary to adopt such suggestions or allow any outsiders to usurp the powers that rightly belong to the members. A resolution will be submitted at the annual meeting to be held at St. Mary's Hall on Wednesday next, the 26th inst., at 8 o'clock in the evening, which practically amounts to a declaration of independence, claiming that the pecuniary position of any applicant for membership shall in future be no bar to admission. Assert your independence by attending and supporting the resolution."

The meeting in question was held in April, 1893. The Mayor of Coventry was in the chair, and he boasted that the dispensary had a balance in hand of from £5000 to £6000 worth of property; he did not, however, say anything about the balance in the hands of the medical men, whose skill and labour had built up this property. Mr. G. A. Bray moved a resolution to the effect that pecuniary position should be no bar to membership. He urged that the time had arrived when "they should definitely and for all time fix their status." He therefore moved :—

"That this meeting resolves that as the dispensary is now a self-supporting institution the pecuniary position of any applicant for membership shall in future be no bar to admission."

Mr. Errington, in seconding the resolution, wished to "make the fact quite clear that in that institution the members paid for what they had," and repudiated the idea of the dispensary being a charity. "There were among the dispensary members men who had been mayor; the committee ballot-box was made by Aldermann Marriott when he was a carpenter, and did these think they were in receipt of charity at any time?" Mr. J. Bill said that he did not agree, and this was the first time after many years that he was in disagreement with the dispensary committee. He thought the pride of rich men should prevent their claiming the medical benefits, but "had they not got absolute evidence to the contrary in the letters to the newspapers? Here was a gentleman coming forward—and he honoured him for his courage—and declaring that he could afford the ordinary medical fees of the outside doctors, but he came here because he thought he was entitled to come." Was the "basis of payment at the dispensary fitted for a rich man"? It was low expressly so as to admit the poor. The institute was founded in a spirit of benevolence. "If they removed that they removed one of the best and strongest supports of the institution. He differed from the proposer of the resolution in this particular: if they let the rich in the poor would be crowded out. It was ridiculous to tell him that the man who said he could pay 5*s.* or 2*s.* 6*d.*, but chose to pay 2*d.* or 3*d.* for a doctor's visit, was a man he ought to honour." Mr. Pears, the only surviving member of the original committee, wrote that the institution was based on philanthropy, and "it was always the desire of the committee, when I was a member and could attend it, to keep *strictly* to the principles of its foundation." The original founders' committee had not only said that the rich people should be excluded, but, Mr. Bill added, they "promised that extra care should be taken to exclude them. ....." "Another point was that the institution possessed £5000 worth of property which was bequeathed to the 'Benevolent and Provident Dispensary."

Hosted by Google

The word 'benevolent' was at the head of it, and that property was left to the institution in that character." Such property was not bequeathed to rich men, yet Mr. Daffern had said, "Not only can I afford to employ a medical man, but I am told that there are scores of people in better positions than myself." Mr. Daffern replied that he joined thinking it was a self-supporting institution and not a charity, and denounced the "impudence" of those medical men who called it a charity. The medical staff was paid. The outside practitioners wished to deny them the benefits of coöperation. It was scandalous to call it a pauperising institution. Canon Beaumont and Dr. Fenton thought the resolution was uncalled for, but were so lukewarm in their half-hearted support of Mr. Bill's opposition that the resolution was carried by an overwhelming majority, only about six hands being held up in opposition. Thus in a most emphatic and public manner was it proclaimed that wealthy persons should not be debarred from joining the dispensary. The discussion also clearly shows that the charitable nature of the medical work is not recognised. Yet if we accept the minimum fee for a consultation at 1*s.* 6*d.*, and if, as stated by Mr. Bill, the medical staff received only about threepence per visit, they make a present of 1*s.* 3*d.* to the institution every time they see a patient. Nevertheless, these patients have the audacity to think that because they pay 3*d.* out of the minimum fee of 1*s.* 6*d.* they are not in receipt of charity. In this respect it is curious to note that when the institution was first established a meeting of the medical men of Coventry was held in this self-same hall (St. Mary's Hall) on July 29th, 1829. Dr. Bourne was in the chair, and the following resolution was carried:—

"1. That this meeting regrets, after a full consideration of the subject, that they cannot approve of the establishment of a self-supporting dispensary in this city, the principles of which, they think, are not adapted to the locality of Coventry. 2. That this meeting would most cordially coöperate with their fellow citizens in establishing a charitable dispensary upon the usual terms of such institutions."

This opposition caused the scheme to remain in abeyance for a while, but in October, 1829, a meeting, under the presidency of the Rev. W. F. Hook, was held, and drew up rules similar to those now in force, except that some restrictions were placed upon the class of person to be admitted to membership. In consequence of the opposition of the profession the self-supporting idea remained in abeyance. Fifteen months later it was decided to incorporate a charitable element. At another public meeting the medical men again opposed a self-supporting dispensary, wisely foreseeing that "the system was open to abuses," and again offering to support a charitable institution. Nevertheless, the committee, while seeking to conciliate opposition, persisted in promoting the self-supporting principle. The medical men, therefore, boycotted the institution and refused the appointments offered to them. The dispensary was obliged to import two medical men—namely, Dr. Nankivell and Dr. Bicknell—who entered upon their functions on June 20th, 1831. At an early date the institution had more than 2000 members. The membership was originally limited to 2500—a very wise rule, as this is not too large a number for a couple of medical men, and differs very remarkably from the 26,000 members mentioned in 1892 as being under the care of only five medical men. After some years these early and wise resolutions were abandoned, and the abuses foreseen by the medical profession so far back as the year 1829 were realised to the full.

(To be continued.)

MANCHESTER.

We have been requested by the honorary secretary of the Manchester Medical Guild to publish the following resolution which was recently passed by the Guild:—

"Having had its attention drawn to the conduct of a 'Dr. Wallace, a graduate of Glasgow,' who (as reported in the *British Medical Journal* of May 29th) has allowed himself to become the agent of a medical aid association at Penge and Beckenham in direct opposition to the expressed wishes of the local profession, the council of the Medical Guild at Manchester desires to place on record its emphatic condemnation of such conduct as this gentleman's, not only as derogatory in itself and indicative of deplorable absence of *esprit de corps*, but also as subversive of the true interests of the public and the profession."

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Workhouse Milk.

QUESTIONS as to the adulteration of milk are continually arising, and the conclusions reached are almost as frequently unsatisfactory in consequence of the various standards adopted by analysts, differing as they so often do from that allowed by the authorities at Somerset House. This was illustrated by an unsuccessful prosecution the other week at Manchester. Samples of milk supplied to the Chorlton Union Workhouse at Withington were examined by Dr. W. C. Williams, one of the assistant county analysts. The first showed 3·22 per cent. of fat and 7·68 per cent. of non-fatty solids. Genuine milk should contain at least 8·5 per cent. of solids other than fat. The second sample showed 2·57 per cent. of fat and 8·32 per cent. of solids other than fat. The third sample showed upwards of 10 per cent. of added water and 7·64 per cent. of non-fatty solids. For the defence it was urged that though probably below the standard of some local authorities, it was not lower than that allowed by the authorities of Somerset House. The presiding magistrate said "the bench had carefully considered the evidence, and, after looking at the analysis, and having considered the variations in the results of analyses by different people they had come to the conclusion that the milk in this case had not been adulterated." It is surely time that the limits of normal variation in the composition of milk should be more clearly defined.

Whitsuntide in Manchester.

In the north of England Whitsuntide is the great holiday of the year, and nowhere is it observed more enthusiastically than in and about Manchester. The great flower show at the botanical gardens, Old Trafford, draws exhibitors and visitors from all parts of the country; the theatres and other places of amusement, such as the Belle Vue Gardens—with their zoological collections and spectacular displays of fireworks—attract thousands of visitors. Perhaps, however, the processions of the children from the various Sunday schools is the feature most characteristic of the people and the place. Monday is devoted to the Church of England schools, represented yesterday by a gathering of more than 24,000. On the other days the scholars attending the schools of other denominations march in procession. In addition to this, almost all the schools organise excursions to places more or less distant, or picnic in fields in the suburbs. If the weather is good, all goes well, but if it rains "they take their pleasure sadly." More thought seems now to be given to the protection of the children from exposure and undue fatigue than used to be the case, but unfortunately the long excursions to Llandudno and such far away places are more popular than shorter ones, so that a very early start has to be made, and in some cases midnight has approached before the children—the younger ones asleep or weary and irritable—have got back to Manchester. "A Whit week *fête* and gala" is being held in Trafford-park, with a varied programme of entertainments, but yesterday several thousands of people had the good taste to find their principal pleasure in rambling amongst the woods and in the meadows of the inner park. This is arranged for by the "syndicate" and not by the city council which lost the park for the people of Manchester.

Artificial Filters for Sewage Purification.

In a report submitted to the Mersey and Irwell Joint Committee, last week, Sir Henry Roscoe said the adoption of artificial filters for the treatment of sewage was a move in the right direction, especially in the case of large towns, where it was difficult to obtain a sufficient area of suitable land for sewage purification. He said that the trials, extending over seventeen months, of filters made both of cinders and coke, for the Manchester Corporation, had been satisfactory. The effluent submitted to filtration had previously been treated with milk of lime and copperas. An acre of filter could deal continuously with about 800,000 gallons per day. "It remains, however, to ascertain how long these filters will work satisfactorily before requiring renewal of a part or the whole of their contents, and this is a cardinal point." To obtain the data required to show if they were efficient for dealing with large

Hosted by Google

populations he advised the Rivers Committee of the Manchester corporation to carry out artificial filtration on a much larger scale than they had done.

District Nurses for Cheetwood, Higher Broughton, and Kersal.

A public meeting was held recently, Alderman Walmsley, M.R.C.S., J.P., &c., being in the chair, under the auspices of the Manchester and Salford Sick Poor and Private Nursing Institution, to consider the advisability of engaging two nurses for the above district. The chairman was supported by the Bishop of Manchester, the clergy and the ministers of various denominations, as well as by the local medical practitioners and other gentlemen. The institution is affiliated with the Queen Victoria's Jubilee Institution for Nurses. It is hoped that two trained nurses may be engaged by public subscription at a cost of £170 a year. From the feeling manifested at the meeting there is little doubt that this modest but useful enterprise will be carried into effect.

June 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Jubilee Day Arrangements in Edinburgh.

IT is hardly necessary to say that the medical classes will not meet on June 22nd. The Royal College of Surgeons of Edinburgh has issued invitations to a Reception at Surgeons' Hall in the afternoon. This, so far as I have heard, is the only medical gathering of a formal kind for which arrangements have been made.

Glasgow University.

The final examination for degrees in medicine and surgery commenced on the 7th inst.; there are 133 entrants, including 11 women candidates. The degree of M.D. has been conferred on Mr. Thos. F. Tannahill, M.B., C.M. Professor McKendrick has been awarded the MacDougall-Brisbane prize by the Royal Society of Edinburgh in recognition of his published researches in connexion with sound and the phonograph.

Faculty of Physicians and Surgeons, Glasgow.

Mr. Edwin Arthur Gibson, M.B., C.M. Glasg., having passed the necessary examinations and been elected by ballot, has been admitted a Fellow of the Faculty.

Medical Appointments.

Mr. Maitland Ramsay, M.D. Glasg., has been elected Professor of Ophthalmology in St. Mungo's College, and Ophthalmic Surgeon to the Glasgow Royal Infirmary and Ophthalmic Institution. Mr. Jas. Henderson Nicoll, M.B., C.M. Glasg., has been appointed consulting surgeon to the Glasgow Hospital and Dispensary for Diseases of the Ear. The following appointments are intimated at the Glasgow Royal Infirmary: W. K. Hunter, M.A., M.D. Glasg., to be physician to the dispensary, and W. J. M. Slowan, M.B., C.M. Glasg., to be extra-dispensary surgeon.

Important Scotch Law Case as to Disinfection.

In Aberdeen Sheriff Court the local authority for the city under the Scotch Public Health Acts petitioned the court for a warrant to take bedding from the residence of a householder to the town council's disinfecting station for purposes of disinfection, three cases of measles having occurred in the house. The judge (Sheriff Substitute Robertson), while admitting that the air or steam method of disinfection is the most effectual if properly applied, held that the provision and use of disinfecting chambers are permissive under the present Public Health (Scotland) Acts, and found, besides, that the householder had disinfected with sulphur fumigation and exposure to sunshine, in accordance with the advice of the family medical man and of a circular issued by the Board of Supervision in 1874, which has not been superseded. The Sheriff Substitute has therefore dismissed the petition and allowed the householder 5 guineas of modified expenses. It may be added that the Public Health (Scotland) Bill now before Parliament proposes to give local authorities compulsory powers in such matters. In the law case referred to an appeal to a higher court is not possible.

Aberdeen Corporation Sea-bathing Station.

Contracts have now been entered into for extension of the baths pavilion, the total of the tradesmen's offers being £7207 odd. New terraces have been laid out at the seaside, the accesses for vehicles and pedestrians have been improved, and an additional number of trees have been planted on the Links (or downs) adjoining.

Aberdeen Hospitals.

Miss Lumsden, hon. superintendent, Royal Infirmary, has resigned. The juvenile patients in the City Hospital are to be entertained on Jubilee Day.

A Donation.

Mr. J. C. Wordie, Oriental Club, London, has, through Dr. Hunter Mackenzie, given a second donation of £100 to the Eye, Ear, and Throat Infirmary, Edinburgh.

June 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

AT a meeting of the Fellows held on Monday, June 7th, for the election of president, vice-president, council, and secretary for the ensuing year the following were elected:—President: William Thomson, F.R.C.S. Vice-President: Robert Lafayette Swan, F.R.C.S. Secretary: Sir Charles A. Cameron, F.R.C.S. Council: Archibald H. Jacob, F.R.C.S., Edward Hallaran Bennett, F.R.C.S., Henry Gray Croly, F.R.C.S., Sir Philip Crampton Smyly, F.R.C.S., Sir William Stokes, F.R.C.S., Henry Rosborough Swanzy, F.R.C.S., Sir Thornley Stoker, F.R.C.S., William Ireland Wheeler, F.R.C.S., Austin Meldon, F.R.C.S., D.L., Sir Charles A. Cameron, F.R.C.S., L. Hepenstal Ormsby, F.R.C.S., Richard D. Purefoy, F.R.C.S., Charles Bent Ball, F.R.C.S., Henry Fitzgibbon, F.R.C.S., Arthur Henry Benson, F.R.C.S., Francis T. Heuston, F.R.C.S., Thomas Myles, F.R.C.S., John Lentaigne, F.R.C.S., and George M. P. Murray, F.R.C.S.

Royal College of Physicians of Ireland.

At the meeting of the Royal College of Physicians of Ireland, which took place on the 4th inst., Dr. James Craig, of the Meath Hospital, was elected to the post of Registrar to the College, vacant by the death of Dr. Guy L. Nugent.

Irish University Education.

Professor Leitch, D.Lit., D.D., the new Moderator of the Irish Presbyterian Church, in his opening address on June 7th made an extremely important pronouncement on the vexed question of Irish university education. Referring to the educational disadvantages under which Presbyterians in Ireland had laboured in the past, and to the destruction of the late Queen's University, and to the fact that the Royal University established in its place was a mere examining board (which therefore necessarily failed to fulfil one of the chief functions of a university) in which Presbyterians were not fairly recognised, he said that if a separate Catholic university was established then the Presbyterian Church might in fairness demand that they should have another university for themselves, with all the privileges which the Protestant Episcopal Church enjoyed in Trinity College, Dublin, and which the Roman Catholic Church will have in their university. Professor Leitch thought such a solution of the question, although a fair and justifiable one, would be disastrous to the best interests of Ireland, as it would tend to sectarianise her education by giving a separate university to each of the three chief religious denominations, because that education which ought to liberalise and unite the people in their national, intellectual, and social life, would become an instrument for widening and deepening and perpetuating those differences by which already they are so unfortunately separated. If the Roman Catholics will be satisfied with nothing but a Catholic university, then Professor Leitch advocated the establishment of one great Protestant university in which all denominations would be united on equal terms, and he thought this might be done by the reconstruction of the government of Dublin University (Trinity College) so that Presbyterians should have an adequate share in it; the affiliating to it of another college or colleges which would be on a level with Trinity College and endowed and equipped commensurately with it; and the making of other financial arrangements with Trinity College which such changes would necessitate. In this way there would be in Ireland a university, like Oxford and Cambridge, composed of a number of colleges, where the most healthy rivalry would prevail. The question is, Would

Hosted by Google

the authorities of Trinity College consent to such a re-arrangement of their university? If they would not, and if the Roman Catholics demand a Roman Catholic university, fully equipped and endowed, then nothing is left for the Presbyterian Church but to claim that whatever privileges and endowments are given to Roman Catholics in the university established for them, the same shall be given to Presbyterians in a third university founded for that body. Such is the scheme put forward by the head of the Presbyterian Church in Ireland, one of her most distinguished professors, and himself a Senator of the Royal University of Ireland. A great deal can be said for and against such a plan for settling the Irish University education question; but the Government, in announcing their intention of devoting a part of next session to Local Government in Ireland, have probably shown that for the present the education problem must be shelved. They are no doubt wisely waiting until the principal parties concerned put forward practical schemes for consideration.

Monaghan Dispensary.

At a special meeting of the Monaghan Dispensary Committee, held on June 3rd, Dr. Henry was unanimously appointed medical officer in place of Dr. Dunwoody, resigned.

The New Victoria Hospital.

The subscriptions to the new Victoria Hospital amount now to about £94,000, so that it is hoped that before Jubilee Day the required sum (£100,000) will be obtained. The arrangements about the Charter of the new hospital and as to its probable site are at present under discussion.

A Local Government Board Inquiry.

Dr. Browne, Local Government Inspector, held an investigation at Lismore with regard to a singular charge brought by a man named Tobin against Dr. R. J. Baylor, the dispensary medical officer of the district. The charges were to the effect that on April 5th Dr. Baylor was drunk when attending Tobin's wife in her confinement, and that on the same occasion he brought into Mrs. Tobin's room a commercial traveller named Appleby and introduced him as a naval medical officer. The midwife in her evidence stated that Dr. Baylor appeared to be drunk, and that from the demeanour of Mr. Appleby in the sick-room she suspected at the time that he was not a medical man. Some of the women who were in the house when Dr. Baylor arrived corroborated the statement of the midwife, that Dr. Baylor introduced Mr. Appleby as a naval surgeon, and expressed their opinion that Dr. Baylor was drunk that night. On the other hand, Dr. Baylor swore positively that he was not drunk, and that as a matter of fact he had taken only two bottles of stout on the day in question. Furthermore, he stated that at the time he believed Mr. Appleby to be a medical student and that he would not have allowed him to accompany him if he thought otherwise. Three witnesses who saw Dr. Baylor that evening swore that he was quite sober. Mr. Appleby, in the course of his evidence, stated that he had never been a medical student, but that he had studied chemistry and had told Dr. Baylor that he had a great taste for the medical profession and hoped some day to be a medical man. He believed Dr. Baylor misunderstood what he said and took him to be a medical student. He also swore that Dr. Baylor was sober. Mrs. Tobin's evidence was then taken. She stated that Dr. Baylor was drunk, and that she heard him introducing the commercial traveller as a naval medical officer when they got into the kitchen. Whilst describing the incidents of the night the poor woman appeared completely overcome with emotion, and before her evidence was completed she fell fainting from the witness chair. Dr. Browne forwarded his report to the Local Government Board, and their decision was communicated to the Dispensary Committee last week. They found Dr. Baylor guilty on both charges and called on him to resign, intimating at the same time that if he should fail to do so they would dismiss him from office by sealed order.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Development in the Medical Use of the X Rays.

AT the meeting of the Academy of Medicine last week M. Combe communicated an ingenious application of skiagraphic methods to the bones of the face. He hangs a delicate photographic film, which has been carefully preserved from contact with the light, upon an artificial palate modelled in vulcanite exactly to the oral cavity of the subject. This, when placed in the mouth, can be maintained in position by the closure of the jaws. The rays from the bulb are directed perpendicularly on the region it is desired to photograph, the exposure being from six to eight minutes. The tube employed is a bi-anodic bulb giving a spark of 45 c.m. The skiagrams obtained showed, among other things, the anterior part of the superior maxillary bone, in which the roots of the incisors and canine teeth were very clearly visible, and in the substance of which the least tumour would have become obvious. Another curious development in x ray photography has been obtained by Messrs. Luys and David, who have exhibited at the Biological Society some skiagrams representing what they term "effluves" given off by the eye and finger in the normal condition, and their results will have much interest for occultists and dabblers in electro-biology. Messrs. Luys and David have employed a new method, which had, however, already been mentioned by Dr. G. Le Bon. It consists in the immersion of the fingers of the subject in an hydro-quinone bath, the fingers being applied by their palmar surfaces to a plaque of gelatino-bromide of silver in the dark for some quarter of an hour or twenty minutes. As a result the observers believe thus to have demonstrated that there emanates normally and continually from the human body during a state of wakefulness a special fluid which they consider "the essential manifestation of life." This phenomenon is similar to that which Colonel Rochas has recently sought to demonstrate under the name of "externalisation of sensibility." To the imaginative all sorts of possibilities will present themselves as the result of the study of this "essential manifestation." By watching the variations of this nerve force taking place in accordance with the age, sex, different times of the day, different environments, and different mental conditions, assistance may be gained in the study of physiology and pathology, while the absence of "les effluves" may possibly furnish that sign for which so many are now looking—an incontrovertible proof of death.

The Toxicity of Human Perspiration.

At the Biological Society also M. Arloing has reported some interesting observations on this subject. He found as a result of making intravenous injections of natural perspirations and also of prepared extracts of the same that when the strength of the injection approached fifteen centimetres per kilogramme in the case of the dog, and twenty-five centimetres per kilogramme in the case of the rabbit, death almost always occurred, generally within three days, though sometimes not for some weeks, when it followed upon a state of profound cachexia. The injection of one-sixth, one-quarter, or one-third of the lethal dose led, according to his observation, to immediate and proportional effects. The toxicity varied with the environment of the subject which furnished the perspiration as well as with the mode of preparation of the extract. The perspiration secreted during arduous muscular toil is richer in toxic principles than that secreted during the ordinary circumstances of life, the degree of extra malignancy amounting to 25 or 30 per cent. All things being equal, perspirations obtained by artificial means of sudation present a minimum of toxicity, but perspiration obtained from a subject who has suffered from retention of the secretion due to cold is poisonous.

The Microbiology of Hospital Wards.

M. Netter communicated at the same meeting of the Biological Society the result of some important researches which he has made and which have revealed the presence of virulent pneumococci in the dust and wards and walls of hospitals. He has collected and examined the dust upon a wall at a point corresponding to the back of the bed of the patient, and over a surface which could not have been directly affected by the coughing of the sick. The dust was collected on April 22nd upon pledgets of cottonwool. On May 19th one of these pledgets was washed with care in sterilised water and the resulting deposits were centrifugalised. The diluted specimen was then used for the inoculation of three young guinea-pigs, two in the peritoneum, and the third in the cellular tissue also. The first subject died on May 25th; the one which had been inoculated at the same time in the peritoneum and the cellular tissue died on May 26th, and both presented all the symptoms of a general fibro-purulent peritonitis. The serous fluids of the body of each contained organisms exactly

Hosted by Google

resembling pneumococci, and cultures in gelatin and in bouillon confirmed the presumption drawn from the appearances.

The Hospital Treatment of Parturient Women.

At the Municipal Council the facilities have been discussed for prolonging the sojourn at the hospitals of women who have been accouched and who are at the present time, except in the case of puerperal illness, compelled to be sent away at the end of ten days with their infants. One establishment alone exists in the environments of Paris, l'Asile Ledru-Rollin, where women can obtain shelter during their convalescence. But this asylum contains only sixty beds, and is consequently altogether insufficient for the wants of the class for which it is provided. M. Colly proposed to increase the duration of the legal sojourn at the maternity hospitals after accouchement. M. Strauss preferred to increase the accommodation at the Ledru-Rollin Asylum. A new maternity hospital is about to be built in connexion with l'Hôpital St. Antoine, and a certain number of beds will be provisionally reserved there for convalescents. A new hospital is going to be constructed also in the south-west of Paris as a result of the enterprise and generosity of the proprietor of one of the largest shops in Paris—the Bon Marché. The hospital will be called the Hôpital Boucicault, after the name of its foundress, and will take gratuitous care of the employés of the Bon Marché as well as of all other sick people who can pay their expenses there. It will be officially opened by the President of the Republic on July 13th.

Professional Responsibility.

A medical man has, I regret to state, been condemned at Paris to two months' imprisonment and a fine of 500 francs for *homicide par imprudence*. His patient died as a sequel to an operation for the removal of a fibroma which had been undertaken without proper precautions.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"Pro Silvis."

THE reafforesting of Italy is one of the most momentous problems before her legislature. The new "legge forestale" (forestal law) has been under examination by a special commission, which has approved its provisions "in massima" (in the main), but not without suggested modifications to ensure its effective working, particularly in the matter of regulated tree-felling. This latter provision has heretofore been honoured more in the breach than in the observance, and what wonder, when the miserable pay of the officers told off to enforce it is taken into account. Inspectors, who go about in pairs and are each mounted, are empowered to patrol the wooded districts, and if they come upon a man felling a tree to demand the certificate authorising him to do so. Their salary amounts to 40 lire a month (about 30*s.* in English money at the current exchange), out of which they have to keep their horse. It has been found that to eke out their scanty pay they are often tempted to ignore the tree-feller's failure to produce the certificate and to share the proceeds of the illegally utilised timber. The law has in many places become a dead letter in consequence of those irregularities, and its revision in the direction of greater stringency is imperative. The whole question is, as I have said, a momentous one, in which (characteristically enough) those chiefly interested are medical men. Now that the late elections have given so many of them a seat in Parliament we may expect a more vigorous, as well as a more thorough, promotion of the long-neglected reform. The classic treatise on the subject is, indeed, of medical authorship. "Pro Silvis: Elementi di Economia Naturale basati sul Rimboscamento" ("A Plea for the Woods: Elements of Natural Economy based on Reafforesting")—such is its title. Its writer was the late Dr. Arnaldo Cantani, Professor of Medicine in the Neapolitan School, a physician and bacteriologist in advance of his time, whose public services in fields allied to that of the healing art procured him his seat in the Italian Senate. Italy, he points out, is essentially an agricultural country, finding her chief source of revenue in the soil, a solid revenue, moreover, not of the factitious kind "which fortuitous circumstances may create or undo." The historic retrospect he gives of the fate of the woods which, in Virgil's time, were among the "praises of Italy" is at once most interesting and most melancholy, the denudation of the hillsides being primarily due to causes, manufacturing and domestic, which, now that she has become a limited kingdom and a "great power," may be expected to increase rather than diminish. How little she realises the extent of the bane and the nature of the antidote may be inferred from the fact that she has but one school of forestry, and that a very backward one—the school at Vallombrosa in Tuscany. In Germany, in Austria, in Switzerland, and in a less degree in France, the agricultural population are taught to balance the tree-felling process by that of planting and cultivation—a knowledge rare in Italy even among her landed proprietors. It is, however, the medical aspects of the reckless clearing away of forest growth, with its atmospheric results and the climatic changes, down to the causation of the floods, which every autumn become a national visitation, that lend the subject now before Parliament its most far-reaching and permanent interest. I hope the Di Rudini Administration will give practical proof of its mastery of the lessons so powerfully driven home by Dr. Cantani, whose work is quite an armoury for those of his medical co-legislators, who are the paladins of this sanitary, economic, and patriotic crusade.

"An Incredible Scandal."

The words are not mine. They are those of an Italian publicist in commenting on the Commission of Inquiry which has recently reported to the Chamber of Deputies on the "fatti dolorosi, enormi, incredibili" (sad, hideous, incredible facts) revealed in the administration of the Foundling Hospital at Naples. This hospital, or "Brefotrofio," as it is called, is, I am sorry to say, a specimen—though an exceptionally ghastly one—of the many institutions of the kind established in the great centres of population where the large celibate communities of both sexes, accommodated in religious houses, are the cause of illegitimacy on an enormous scale, the hapless offshoots of which find their way as "foundlings" into the said hospitals, where, if they are not "killed outright," they can hardly be meant to live. The mortality thus occasioned has long been a scandal, though it has seldom, if ever, attained the total given by the Commission of Inquiry in its report on the Neapolitan "Brefotrofio." In the last two statistical years the foundlings admitted into that institution were 856, and their deaths at the close of 1896—the second of those two years—amounted to 853! In other words, the survivors of the "system" were, all told, three! That something hideously wrong prevailed throughout the management of the "Brefotrofio" as a whole had long been more than suspected. The "corpo sanitario" (sanitary authorities) of Naples made repeated attempts to get at the truths officially veiled, but all in vain. There was reason to know that every hygienic law in the institution was "honoured in the breach," not "in the observance"; that the dormitories were positively foul with untidiness and neglect; that the management made absolutely no provision for "sale d'isolamento" (isolation rooms) on the frequent outbreak of infectious or contagious disease; that no addition was made to the wet nurse service when the foundlings were admitted in larger numbers; that, for instance, one nurse was allowed to give the breast to as many as four infants per diem; that the hot-water boiler was unknown in the building; and that the baby linen was as filthy as it was deficient, seldom renewed, and still more seldom washed. Nor is this all. The Commission of Inquiry reports that the milk (cow's or goat's) was never sterilised; that the feeding-bottles were never disinfected, and that a stop was put to the dispensary from which medicines and sick-room necessaries were gratuitously supplied to the out-door nursing service. Worse still remains to be told. In order to relieve the institution of its tiny inmates—as if death did not complete its task quickly enough—the management (so says the Report) trumped up against those of them who had reached seven years of age charges of insubordination or other offences grave enough to relegate them to houses of correction! "Thus," comments the Cavaliere Perrone, chairman of the Commission, "by condemning the child to associate with young thieves and lawbreakers recruited from the worst classes, you bring about his 'civil death,' in the rare event of his having succeeded in escaping 'natural death.'" And so, from the first page to the last, the Report accumulates proof upon proof of criminal violation of all the rules that ought to control such institutions, while the debate it evoked

Hosted by Google

in the Chamber of Deputies on the 2nd inst—a debate headed in the parliamentary reports, "Gli Orrori del Brefotrofio di Napoli" (The Horrors of the Naples Foundling Hospital)—drew from several speakers the demand that the "administrators" should be prosecuted to conviction. These "functionaries" have all resigned, and the Minister of Grace and Justice has undertaken that they and their conduct shall come before the tribunals.

The Italian Karlsbad and its Chief Promoter.

Attention has from time to time been drawn in these to columns Italy's wealth in mineral waters, and particularly to those of the Tuscan Monte Catini, known as the "Italian Karlsbad," for their efficacy in hepatic disorders and in the initial phases of gout. Next to the name of Fedeli, the most honourably associated with Monte Catini has of late years been that of Federici, to whom the thermal establishment owes many substantial and enduring services. That eminent physician, who held one of the clinical chairs in the Florentine school, died in 1892, when a full account of his career was given in THE LANCET.[1] On Sunday, May 30th, a commemorative tablet, inserted in the façade of his house in Florence, was unveiled in the presence of a large concourse of the public, professional and lay, the medical schools throughout the kingdom being nearly all represented, and the spokesman of the occasion being his successor in the Direction of Monte Catini and in the Florentine chair, Dr. Pietro Grocco, the acknowledged head of Tuscan medicine. The text of Professor Grocco's speech is now before me, and I need only say of it that it is equally honourable to its subject and to its author. The Italian intellect at its best never appears to greater advantage than in the medical field, whether in enlarging the scientific horizon or in adding to the resources of practice. Cesare Federici was one of those worthy successors of Baglivi and Morgagni, Rasori and Nobili, who have left indelible traces on the evolution of the healing art, and his example was effectively utilised by his successor as a stimulus to the medicine of young Italy to follow the same independent and painstaking line. A few more leaders of his stamp, and the ground she has lost since the Renaissance would be not only retreived but extended, to the development of her professional efficiency all round and especially of her resources in balneary methods of treatment wherein her native advantages have hitherto been inversely to her energy in utilising them.

June 5th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Budapest Humane Society.

A MEETING was held on Sunday last in the new town hall of Budapest, the occasion being the tenth anniversary of the foundation of this society. The meeting was honoured by the presence of H R.H. the Archduke Joseph, the patron of the Humane Society, and by his Excellency M. Wlassics, Minister for Public Instruction. The Mayor of Budapest, Count Lamezan, the President of the Vienna Humane Society, and most professors of the medical faculty were also present. The Budapest Humane Society was founded ten years ago by the philanthropist, Chevalier S. Falk, Count A. Andrássy, and its present director, Dr. G. Kresz, and has since risen from small beginnings to an organisation which brings help and comfort to thousands whose lives are in jeopardy. During last year the society was called upon in 13,251 cases. The whole number of cases in which its assistance had been resorted to during the ten years of its existence amounts to 81,315. The society has also done very good work in establishing and organising similar institutions in the larger provincial towns of Hungary, such as Kolozsvár, Székesfehérvár, Szabadka, and Nagyvárad.

The First Hungarian Lady Doctor.

Last week Countess Hugonnay took the degree of M.D. of Budapest University. She completed her medical curriculum and graduated as M.D. in Switzerland some years ago, but was not allowed to practise in Hungary, because, according to law, foreign degrees—save those of Austria—cannot be entered in the Hungarian Medical Register. She had, therefore, to pass the final examinations of Budapest University, and I understand that she will practise in Budapest as an obstetrician and gynæcologist.

Long Forceps (Axis Traction) versus Turning.

Dr. St. Tosh has published out of the rich material of Professor Tauffer's Obstetrical Clinic a series of cases in which he employed long forceps instead of turning. The conclusions he drew in his very elaborate paper were the following: — 1. The use of the forceps at the inlet of the pelvic cavity is not so hazardous as is still believed by many writers, and is decidedly more favourable to both mother and child than internal podalic version. 2. In all cases where speedy delivery is required for the safety of the mother and version is not applicable the axis traction forceps should be tried before resorting to perforation. 3. In cases of moderately contracted pelvis long forceps are to be preferred to turning, because by thus waiting the expulsive powers have a chance to complete labour spontaneously. 4. Should the forceps at the inlet prove of no success, then perforation is to be performed at once. Symphyseotomy may under favourable circumstances prove to be the right proceeding, but internal podalic version is decidedly contra-indicated in these cases. 5. Axis traction forceps of different lengths may be used, but Dr. St. Tosh prefers Tarnier's instrument.

June 3rd.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Pilgrims and Quarantine.

DR. ARMAND RUFFER, the new President of the International Quarantine Board of Egypt, has just returned from the pilgrim camp at Tor. In order to be prepared for the influx of returning pilgrims he had established a large staff of European and native medical men, some of the latter having been temporarily lent by the School of Medicine here. For the first time, also, an Englishman is being employed there, Mr. Chilton. Orders were given that during the three days' quarantine, which every pilgrim is obliged to undergo at Tor, all cases of diarrhœa should be viewed with suspicion and examined bacteriologically. On May 24th, as a matter of routine, a miserably sick man moribund from kidney disease was so examined. The medical officers who conducted the necropsy declared their conviction that it could not possibly be a case of cholera. Yet microscopical examination of the fæces revealed the typical comma bacilli, which were so familiar a year ago in Cairo to some of the workers now at Tor. In some other cases of diarrhœa, among the living and the dead, bacilli of cholera could not be discovered; while, on the other hand, they were found in some cases where diarrhœa was not a prominent symptom. So far cholera bacilli have been found in eight pilgrims during the last week, though the telegraph reports that there were no fresh cases yesterday. Now all these cases of comma bacilli were similar, and all behaved in the same way to various tests employed. For instance, the suspected substance gives the indol reaction with sulphuric acid added to peptonised bouillon, and the addition of cholera serum to an emulsion of the organism produced a flocculent precipitate. Yesterday as a further proof Dr. Symmers and Dr. Bitter inoculated three guinea-pigs with material brought from Tor. All three died within six hours, their temperature falling within three hours after injection from 99·2° F. (two) and 101·5° to something below 95°, which the thermometer could not register. To-day, again, three more guinea-pigs were inoculated with a fatal dose of the bacillus, together with varying quantities of cholera serum (Pfeiffer); but the result of this is not yet known. This is the case for cholera: much diarrhœa, a few deaths, and unmistakable bacilli found in eight patients. The arguments against cholera are that the bacilli are not yet corroborated by clinical, pathological, or epidemiological evidence. So far, it is said, there is an absence of vomiting, cramps, cyanosis, and rice-water stools, and the intestines of the dead are found filled with bile-stained fæces. Dr. Zachariades, who is in medical charge of Tor, has seen three cholera epidemics there, and firmly denies that the present disease is cholera. This is based upon his own clinical opinion, but it is interesting to remember that he was the medical man who in 1895 reported that cholera was then existent at Tor. His French colleague was unable to find any

[1] THE LANCET, June 4th, 1892, p. 1278.

Hosted by Google

bacilli. The Quarantine Board in Alexandria supported the bacteriologist and gave no credence to the clinical report. Officially there was no cholera at Tor in 1895, and yet the disease was introduced about that time into Egypt and remained in the country till October, 1896. Up till now the Quarantine Board has declared the present pilgrimage to be "clean," but it is difficult to see how they can now avoid declaring it "unclean." In this latter case all existing and future pilgrims will be kept at Tor for ten days after the last case. By decision of the various congresses a pilgrimage must be in one of these two categories—it cannot be classed "suspect." By declaring it "unclean" some inconvenience would be caused to quarantine officials and to about 2000 pilgrims, but, on the other hand, Egypt would very likely be saved from another outbreak of cholera. Cholera always has entered Egypt from Hedjaz, though it has never been discovered at the time. Also, it must be remembered that cholera has often been at Tor, as in 1890 and 1891, without the disease entering Egypt. Past history tells us that when the quarantine officials have recognised cholera and treated it energetically Egypt has not been attacked. On all occasions when Egypt has suffered from cholera the enemy has been allowed to penetrate the first line of defence without question. At this crisis we may congratulate ourselves that Dr. Ruffer is at the head of the Alexandria Board and that he happened to be inspecting Tor last week.

Unruly Pilgrims.

A few days ago a temporary rising took place at Tor among pilgrims, who naturally demurred at any extension of their quarantine. One of their grievances is that they have to supply themselves with food during their imprisonment in camp. At the time of this rising eighty Egyptian soldiers were guarding 5000 Turks. To any one who knows the two races this is like setting a sheep to watch the dogs. Now the guard has been doubled, and what is obviously wanted is an English officer in command.

Cairo, June 1st.

Obituary.

ROBERT MUNDY GOVER, M.D. ST. AND., F.R.C.P. LOND., LATE H.M. MEDICAL INSPECTOR OF PRISONS.

WE regret to have to record the death of Dr. R. M. Gover, which took place at Falmouth on the 5th inst. Dr. Gover was in the active discharge of his duties until July of last year, when illness compelled him to take leave of absence, and to go to the south of England in search of health. It had been noticed for some time that his health was not good, but it was hoped that rest and change would restore him, and that he would soon be able to resume his duties. Unfortunately these hopes proved fallacious, the desired improvement did not occur, and in December last he felt obliged to place his resignation in the hands of the Secretary of State. The news of his death will come as a shock to his friends, and more particularly to those who were associated with him in the work of the prison department. Dr. Gover qualified as M.R.C.S. in 1856, and L.S.A. in 1859. He became M.R.C.P. in 1876, M.D. St. Andrews in 1882, and F.R.C.P. Lond. in 1883. He joined the prison service at Portsmouth in 1857, and was transferred as resident surgeon to Millbank Prison in 1860. A few years later, in 1865, he succeeded to the full medical charge, and held the position until appointed to the Home Office in 1878. Millbank during his tenure of office there was one of the most important prisons in the country, and his post was no sinecure. He had to deal with all sorts and conditions of criminals, and he became familiarised with all aspects of criminal life. Not only were ordinary offenders confined within the walls, but there was a department for military prisoners, and it was the custom to send lunatics, imbeciles, and epileptics from other prisons for observation and report. The requirements of this large and varied population, their diseases and weaknesses, their excesses and "breakings out," their malingering and grumbling, all kept him busy, and he had not time to contribute much to contemporary literature. Many pertinent observations and valuable suggestions regarding the connexion between lunacy and crime are, however, to be found in his annual reports. The experience thus gained proved of great value to him in the discharge of his more important duties as medical inspector. He was appointed to this post in 1878, a year memorable in the history of prisons, as it was then the local prisons came under the Crown. The transference from the local authorities to a central board of so many large institutions was a work of considerable magnitude, and one requiring the exercise of great tact and discretion. Dr. Gover shared in the work, for there were many medical points which had to be dealt with. One of the most important of these was the introduction of a uniform scale of diet in all the prisons of England and Wales. This subject was submitted to a committee, of which Dr. Gover was a leading member. He displayed great interest in the subject, and published his views in a paper read before the Society of Arts in 1878. During the whole of his career as medical inspector, about eighteen years, the question of prison dietary frequently occupied his time and attention, and he introduced improvements wherever practicable. On many other questions affecting the well-being of prisoners—e.g., the treatment of weak-minded and imbecile criminals, the management of infectious diseases in prisons, &c., he has left traces in the orders which are issued for the guidance of the officials. He had frequently to advise the Home Secretary and the high prison officials in matters of difficulty and delicacy. He gave important evidence before the Commission which inquired into the subject of criminal lunacy in 1880, and he appeared as a witness before the Commission of Inquiry regarding the management of Prisons in 1896. He contributed papers on the treatment of criminal lunatics and weak-minded prisoners to the Paris Penitentiary Congress in 1895. Dr. Gover's manner was gentle and unassuming, and his courtesy and affability were constant. He was held in much esteem by the medical staff of the prison department, and they cannot but regret the loss of one who, as far as lay in his power, upheld their interests and invariably proved a good friend and a kind chief.

JOSEPH LAW, M.D. EDIN., L.F.P.S. GLASG.

DR. LAW, of Sheffield, who died at his residence in Devonshire-street at the great age of ninety years on June 1st, was a veritable link with the past. He was a native of Sheffield, where his family had long been established. His medical education was received at Trinity College, Dublin, and at Edinburgh University, and he became a Licentiate of the Faculty of Physicians and Surgeons of Glasgow as long ago as 1831. He returned to Sheffield, and about 1836 obtained the appointment of house surgeon at the dispensary in West-street, where he remained until, in 1841, he became house surgeon at the general infirmary in succession to Dr. Ernest, who died after more than thirty years' tenure of office. After eleven years' service as house surgeon, during which he was frequently complimented by the governors at the annual meetings, Dr. Law resigned his position, returned to Edinburgh in 1853 for the purpose of taking his M.D. degree, and thereupon established himself in practice in Sheffield. In 1854 he was elected physician to the dispensary and in 1866 physician to the infirmary. On his resignation of the latter appointment in 1876 he became consulting physician, and on his final retirement in 1890, forty-nine years after he had first become connected with the institution, he was presented with a portrait of himself, which was hung in the infirmary board-room. Another portrait of him, executed in 1892, hangs in the Medical School. Dr. Law outlived his wife and his early associates, and witnessed many changes in medicine and surgery. He will be regretfully remembered by numerous friends and acquaintances, to whom his sincerity and goodness of heart endeared him.

THE CIVIL RIGHTS DEFENCE COMMITTEE: PUBLIC MEETING AT PLYMOUTH.—By the help of the members of the Plymouth Medical Society and other medical men in Plymouth both political parties have combined to form an influential committee drawn from the towns of Plymouth, Devonport, and Stonehouse, which committee has convened a meeting to be held on June 14th to receive a deputation from the Civil Rights Defence Committee and hear an address from Mr. R. B. Anderson.

Huxley Scholar: Mr. F. B. Pinniger. Epsom Scholar: Mr. L. C. Badcock. University Scholars: Mr. H. S. Clogg and Mr. R. J. Willson. Huxley Medal and Prize of £10: Mr. A. G. Pitts. Golding Prize: Certificate and £10, Mr. C. J. Mercier. Pereira Prize: Certificate and £5, Mr. S. W. Garne. Anatomy (Senior): Prize, Mr. A. G. Pitts. Anatomy (Junior): Prize, Mr. A. G. Payne. Biology: Prize, Mr. F. B. Pinniger. Chemistry: Prize, Mr. C. J. Mercier. Physiology (Senior): Prize, Mr. A. G. Pitts; Prize (Special), Mr. B. A. Nicol. Physiology (Junior): Prize, Mr. D. Gray. Medicine: Prize, Mr. H. S. Clogg. Surgery: Prize, Mr. E. L. Lilley. Practical Medicine: Prize, Mr. W. H. Unwin. Materia Medica: Prize, Mr. M. G. Hannay. Osteology: Prize, Mr. F. M. Boclet. Practical Chemistry: Prize, Mr. F. R. Bishop. Psychological Medicine: Prize, Mr. V. S. Partridge. Midwifery: Prize, Mr. S. W. R. Colyer. Pathology: Certificate, Mr. W. H. Park. Public Health: Prize, Mr. S. H. Berry. Therapeutics: Prize, Mr. H. W. Abbott. Practical Midwifery (Summer): Prize, Mr. A. E. Weld. Practical Midwifery (Winter): Prize, Mr. W. E. Morgan. Dental Surgery: Prize, Mr. W. Green.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—The annual meeting of the Western Branch No. 1 of the London and Counties Medical Protection Society was held on May 27th at Southerton House, Hammersmith, by permission of its President, Dr. Alderson, who took the chair. After the annual report was read and approved, Dr. Heron, treasurer of the society, said that during the past twelve months there had not been any important legal proceedings, but a very large amount of important business had passed through the society's office. With regard to the subject of hospital abuse Dr. Heron was of opinion that abuse did exist to a material extent, for over 1,300,000 people received assistance every year in the out-patients' department alone of the London hospitals. Put into other words, this meant that almost every fourth person one met in the streets of London was a recipient of hospital charity. In Dr. Heron's opinion the remedy for this state of affairs lay to a large extent in the hands of the medical profession in London; and if they did not help themselves they could not expect other people to help them in their difficulties. He also thought that medical men should give up dispensing medicines, and then, but not, he thought, till then, they would be in a position to take action in the matter of prescribing by druggists. As regarded the conduct of medical defence, Dr. Heron stated that he had always held it should be carried out by one large and powerful society, but he had not heard of any scheme which was likely to lead to this being efficiently done in the near future. After some remarks from the chairman and others the meeting closed with a vote of thanks to Dr. Alderson for presiding.

A MEDICAL MAN'S JUBILEE.—An interesting occasion was the celebration at Esher some fortnight ago of Mr. Izod's jubilee. Mr. Izod, who has been in practice for fifty years at Esher, gave two entertainments in aid of the Prince of Wales's Hospital Fund, and bade the members of the local Fire Brigade and the stewards of the entertainments to dinner afterwards, when the proceedings were of an enthusiastic character.

A DAY OF REST FOR LONDON NURSES.—On Thursday, June 3rd, the nurses of the metropolitan hospitals and nursing institutions were invited by Canon Burnside to spend a day in the country at Hertingfordbury. The object in view was not only to afford some relaxation from work, but to exalt the Christian aspect of the ministry of nursing. There was a large attendance. The day commenced with a celebration of the Holy Communion in the parish church at 10.30. The Bishop of Wakefield was celebrant, and was assisted by Rev. W. Ostle, chaplain of St. Bartholomew's Hospital; Rev. A. G. Locke, chaplain of St. George's Hospital; Rev. H. J. Fase, chaplain of Westminster Hospital; and the Rector. At luncheon time the nurses were well entertained, and in the afternoon, by the kindness of the Countess Cowper, the whole party was invited to Panshanger, where they took tea, and afterwards had the opportunity of seeing the beautiful collection of pictures and strolling through the gardens and park on their way home. The Rev. A. G. Locke, of St. George's Hospital, acted as secretary in making all arrangements for the journey of the nurses from London. Looking back upon the day it was generally felt that, the main object being steadily kept in view, the opportunity had been most helpful in deepening in the mind of many a higher sense of the dignity of the nurses' calling, whilst the recreation and enjoyment of such a visit to the country had tended in no small measure to lighten the strain incidental to a nurse's work.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Poor-law Officers Superannuation.

THE House of Commons has passed through all its stages a Bill to amend the Poor-law Officers Superannuation Act of 1896, so that nurses may signify their intention not to avail themselves of the provisions of that Act, and thus retain intact their salaries or wages, and stand entirely outside the scheme of superannuation.

Infant Life Protection Bill.

This Bill having passed the House of Lords is now in the House of Commons, where it has been put down for second reading on Thursday, June 17th.

Scotch Public Health Bill.

The Grand Committee of the House of Commons on Law completed the consideration of the Scotch Public Health Bill on Thursday, June 3rd, and on the same day the Bill as amended by the Committee was reported to the House by Sir James Fergusson. The Bill in this form will now be printed, so that every one interested may see exactly what the Committee has done, and prepare for the report stage in the House, which has been provisionally fixed for Thursday, June 17th.

HOUSE OF COMMONS.

THURSDAY, JUNE 3RD.

Lights after Dark.

Mr. Melville asked the Secretary of State for the Home Department whether his attention had been called to a verdict of manslaughter given in the case of a bicyclist who was killed at Stockport by a cart driven at night without lights? And whether he would be prepared to introduce a Bill to enforce the carrying of lights and prevent similar accidents in the future?—Sir Matthew White Ridley said his attention had not been called to the case otherwise than by the hon. Member's question, but he was afraid he could not undertake to bring in a Bill. The matter, however, was already before the House, for a Bill providing that all vehicles should carry a light after dark had been discussed and read a second time. Under the existing law borough and county councils had ample powers for dealing with the matter by means of by-laws, powers which in many cases had been exercised.

Flogging Prisoners.

Mr. Joseph A. Pease addressed questions to the Home Secretary and the Under-Secretary for War with reference to flogging in civil and military prisons, and received an assurance from these two Ministers that more information on the subject will be forthcoming.

The Vaccination Question.

At this sitting a Bill was introduced and read a first time "to amend

Hosted by Google

the vaccination laws by providing a compulsory supply of calf lymph under Government control and for other purposes." The Bill is backed by Mr. Carlile (who introduced it), Sir Cameron Gull, Mr. Bemrose, Mr. Howell, and Mr. Wanklyn. The second reading of the measure has been put down for Wednesday, July 7th.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (14th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40 Leicester-square, W.C.).—8 P.M. Annual Meeting: Election of Officers. Paper:—Dr. J. E. Grevers (Amsterdam): Notes on Various Forms of the Articulation of the Upper and Lower Teeth (illustrated by lantern slides).

WEDNESDAY (16th).—NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8.30 P.M. Demonstration of Clinical Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (14th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. G. Stoker: Impaired Movements of the Vocal Cords.

TUESDAY (15th).—ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Savoy, W.C.).—5 P.M. Dr. W. Hale White: The Means by which the Temperature of the Body is maintained in Health and Disease. (Croonian Lecture.)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Pemphigus and Allied Affections.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Gowers: Clinical Demonstration.

WEDNESDAY (16th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Infectious Diseases.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. A. Whitfield: Differential Diagnosis of Sore Throats.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Mr. Godlee: Surgical Lecture.

THURSDAY (17th).—ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Savoy, W.C.).—5 P.M. Dr. W. Hale White: The Means by which the Temperature of the Body is maintained in Health and Disease. (Croonian Lecture.)

LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Methods of Search for Specific Micro-organisms.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Cantlie: Sprue, Tropical Sore Mouth, and Diarrhœa.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square).—5.30 P.M. Dr. A. Eddowes: Ringworm and Favus.

FRIDAY (18th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.)—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Erysipelas and Suppuration.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ormerod: Hemiplegia.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"AN UNUSUALLY HEAVY HEART."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 29th, p. 1466, Dr. G. A. Reid gives an account of a heart which weighed 41 ounces, and two others of 31 ounces and 31½ ounces. He quotes two other cases, one by Delafield and Prudden of 50 ounces and one by Dulles of 48 ounces. He then says, "So far as I can ascertain from the literature on the subject at my disposal no other heart over 40 ounces in weight has been recorded." If he will refer to Taylor, fourth edition, p. 484, he will find one of 48 ounces, and in Osler, second edition, p. 665, he will find one of 53 ounces.

I am, Sirs, yours truly,

Wandsworth, June 3rd, 1897. A. S. MORTON.

THE AUDITOR AND THE WATER DIVINER.

THE Local Government Board auditor, in disallowing the amount of a payment made to a water diviner by the urban district council of Ampthill, Bedfordshire, said that there was no legal objection to the making of experimental borings under competent advice, but no proof that the water diviner possessed special knowledge had been submitted to him, and he held it to be illegal for the council to spend money on speculative enterprises. It was stated that Mr. Leicester Gataker, the water diviner, walked slowly over the ground with his arms spread out, and indicated the position of a spring by stopping suddenly as if he felt a shock. The chairman of the council informed the auditor that in this way a number of springs were found in one field, but on the other hand some dissatisfied ratepayers argued that the spot selected by the diviner was not likely to yield water as the underlying stratum was a bed of clay of great thickness.

Dr. J. Laird.—It would be a great pity to start a newspaper correspondence on such a subject. All such discussions impair the public utility of the profession. The matter is one for discussion between the parties, when facts might be elicited that would give a different appearance. A third medical man known to both should be made a medium of interchange of views, and, if possible, be given the power of an arbitrator.

"WANTED A SURGICAL PHIDIAS!"

To the Editors of THE LANCET.

SIRS,—With reference to the letter referred to in the enclosed cutting from the *Church Family Newspaper*, may I venture to take your correspondent quite *au sérieux*, and say that if he will put himself in correspondence with me, I will guarantee to remove his dissatisfaction without any charge.

Like himself I am a thorough believer in all that surgery can do; and though I do not profess to alter his physiognomy either by any series of surgical operations or in a day, I shall only be willing to undertake his case on condition that he gives to me the "readiness to suffer considerable pain," and his willingness "to run a fair amount of risk" which he offers to fantastic surgery.

One so seldom comes across a soul in earnest, that when such a *rara avis* turns up one's desire is to put his earnestness to the test and to foster a courage by no means contemptible.

You, Sirs, inserted this letter with apologies and a smile; will you accept mine on the same terms? While I assure you that my offer is neither that of a quack nor a catch-penny, I enclose my name for our dissatisfied friend should he write and ask you for it, and to assure you of my *bona fides*, and can only say that with such coöperation as he offers there is no reason whatever to doubt that his face may yet become, in spite of all its defects, the face of an angel.

I am, Sirs, yours faithfully,

June 8th, 1897. EARNEST PHYSICIAN.

*** In accordance with our correspondent's desire, we insert, apologise, and smile.—ED. L.

Curious.—There are by-laws in some of the Colleges which would preclude trading. Permissible or otherwise, such trading is objectionable.

THE ABUSE OF TOBACCO.

THE French Society for the Prevention of Excess in Tobacco, to which we referred in an annotation in THE LANCET of June 20th, 1896, p. 1734, continues to flourish exceedingly under the fostering care of its president, M. Decroix, and its general secretary, Dr. Gélineau. At a recent meeting for the distribution of prizes, which was somewhat incongruously held in the Horticultural Hall, Paris, under high patronage, including that of M. Steeg, inspector-general of public instruction, the funds in hand were said to exceed 90,000 francs, included in this handsome sum being 2000 francs from the president, who regularly devotes his savings as a pensioned veterinary surgeon to the extinguishment of tobacco smoke. The name of Dr. Gruby, who not only presided at the last annual meeting but also offered a prize to the deviser of the best method for breaking a tobacco-chewer of his expectorant habit, is absent from the proceedings on the last occasion, but we sincerely trust that this is not due to any backsliding on his part. The tenets of the society are still as remarkable as ever by reason of their moderation. Being people amenable to reason, the anti-tobacconists recognise the fact that adult mankind is not to be coerced in the matter of the divine weed. The correction of grown-ups being admittedly hopeless they confine their propagandism to the rising generation, and seek to safeguard the innocent babes in the primary schools by revealing to them the awful abysses that are supposed to yawn beneath the, at all events fragrant, pall emitted by countless cigars and pipes. To this end a prize was offered for the best practical means of preserving infancy from the contamination of tobacco, but although a M. Géry, a schoolmaster, was proclaimed the winner and duly crowned as anti-nicotian laureate, the essay upon which he rode to fame has not been reproduced. In like manner a reward of 300 francs was promised some time ago to whomsoever should make known the influence of tobacco on the action of internal medicaments as well as on the cicatrisation of external wounds, but, unfortunately, in this case too we are left in the dark regarding the result. In the course of the proceedings two announcements may, in theatrical parlance, be said to have brought down the Horticultural Hall. The first, by M. Steeg, was an assurance that the ministerial mind was in sympathy with the society; the second, by Dr. Gélineau, was to the effect that in future the bicycle would be employed as a powerful opponent of tobacco.

Killochridge should apply for information to Dr. A. G. Bateman, secretary to the Union, at the offices 20 and 21, King William-street, Strand, W.C.

INCUBATORS.

To the Editors of THE LANCET.

SIRS,—Could some of your correspondents give me any information as to where incubators for babies could be procured in England, and their approximate cost either to purchase or hire?

I am, Sirs, yours faithfully,

June 8th, 1897. H. G. C.

*** Our correspondent will probably be able to obtain the information he requires at the Earl's Court Exhibition. (Vide THE LANCET, May 29th, 1897, p. 1490.)—ED. L.

Hosted by Google

"THE PUBLIC HEALTH EXAMINATION AT CAMBRIDGE."

To the Editors of THE LANCET.

SIRS,—I suppose your correspondent "Examiner" wishes us to infer that he is one in authority at this examination. If he is it is a pity he has no apologies to offer but only flippant remark and subtle sneer. He is astonished at candidates' impudence in expecting to be provided with the usual apparatus, but he is willing to waste their time over unnecessary mental arithemetic. "Examiner" will be surprised to hear "N.D." and "W. T." were considerate enough not to exhaust the catalogue of deficiencies—for instance, to mention that in practical bacteriology thirty candidates had only six or seven oil immersion lenses between them, and these attached to old pattern microscopes without coarse adjustment, and so on. However, I refuse to think that "Examiner's" letter is typical of the attention a candidate's reasonable criticisms will meet with at Cambridge, but I even venture to hope that the letters of "N.D." and "W.T." will prompt the syndicate to improve the laboratory equipment.

I am, Sirs, yours faithfully,

June 8th, 1897. W. T.

*** The letter to which our correspondent refers was signed Examin*ee*, not Examin*er*.—ED. L.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Examinee" cannot have had my letter before him when he penned his letter to you or he would have learned from it that I did not fail in laboratory work as he seems to infer. It was the paper in bacteriology which did for me. To repeat the substance of my letter, I complained of the damaged condition of the oil immersion microscope and its being placed in the centre of the room on an uneven zinc-covered table. I believe there was a vacant room adjoining with abundance of light where the microscopes might have been placed. In the second place I had a special paper on bacteriology, which I had not before when I scored enough marks for a pass in this subject only. This time I was informed I had marks to spare in hygiene, which, had the questions on bacteriology been included with those on the general subject as before, would no doubt have totalled sufficient for a pass in the whole of Part I. Your correspondent will perhaps now understand that I responded successfully to the tests on the laboratory work. If I had not had a course of instruction in such work I dare say I could not have done as well as I did. I quite agree with him in his remarks on the letter of "W. T.," as I had nothing to complain of as regards the arrangements in the chemical laboratory, except the waiting for reagents. I think it, however, bad taste to crow over us because he has passed and we have failed. Everybody knows, and persons of experience in examining students will corroborate the statement, that many good men are ploughed at an exam., and others not so well informed generally, but crammed with knowledge imbibed specially for the purpose of getting through the examination, fortunately for themselves do so.

I am, Sirs, yours truly,

June 5th, 1897. N. D.

General Practitioner.—The general practitioner should have been advised as to the situation by the family. It is not in accordance with professional etiquette for the consultant to take over the general practitioner's patient, but perhaps he has not done so or perhaps he has done so in error. He should be asked in a friendly way what has happened. We do not attach much importance to the solicitation of a subscription, nor does our correspondent say that the consultant knew him to be also a supporter of the charity.

"PASSING RICH ON FORTY POUNDS A YEAR."

THE Hampstead board of guardians appear to place little value on medical services. It is humiliating to read in a daily contemporary, which we trust has been misinformed, that last week they decided to apply to the Local Government Board for permission to appoint a resident medical officer at the workhouse infirmary at a salary of £40 per annum, with board and apartments. He is to have the double qualification and will be required, in addition to his medical work, to do all the dispensing required for the workhouse. The salaries of other officials at the workhouse are—porter, £30 per annum; superintendent of nursing, £50; master, £60; and matron, £60.

Ethics.—(1) The practice of "touting" implies the employment of a tout, and we do not see any evidence of this. (2 and 3) We think that the publication of our correspondent's name is being used as an inducement to people to ask for information concerning the club, so that its appearance in the advertisement is unfortunate. The fact that the magazine has a small circulation and the club a good object does not obviate the fact that the marked passage is an advertisement.

THE MORAL EDUCATION OF BOYS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers furnish me with the title of a book published some fifteen or twenty years ago on the moral education of boys (in connexion with sexual matters)? If my memory does not deceive me the author was the headmaster of Londonderry School.

I am, Sirs, yours faithfully,

June 6th, 1897. FATHER.

HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I have received the following donations towards the funds of the above Association in answer to the appeal in THE LANCET of last week.

Dr. J. G. Glover	£2 2 0
Mr. D. B. Balding, F.R.C.S. Eng....	1 1 0

I am, Sirs, yours faithfully,

June 9th, 1897. T. GARRETT HORDER, Hon. Secretary.

Lex.—1 and 2. We think that the course indicated by our correspondent would be arbitrary. The legal position under these and similar Acts generally depends upon decisions, and we will inquire what decisions are in existence. 3. For obvious reasons the medical man in charge of the hospital should have the patient under his care. There is no slur whatever in this on the skill of the practitioner. *Vide* THE LANCET pamphlet on "Difficulties under the Infectious Disease (Notification) Act."

"INVERSUS" WOOLLEN UNDER-CLOTHING.

MR. D. GILBERT, of 7, Buckingham Palace-road, London, S.W., has submitted to us samples of his "Inversus" woollen under-clothing, both vests and drawers, in the making up of which, contrary to the usual custom, the smooth surface of the material is placed next to the skin, thus meeting the difficulty of those whose sensitive skins will not permit of their wearing the ordinary woollen garment by reason of its irritating effects. The material of the articles submitted to us is of pure, undyed wool, of exceptional smoothness—in fact, the claim of Mr. Gilbert that it is as "smooth as silk" is, we think, worthy of corroboration, there being an entire absence of those knots and teazles usually met with in woollen under-clothing. The material is manufactured in two substances—(1) thin, for summer wear, and (2) medium thickness, for spring and autumn wear.

Fair Play all Round.—Our correspondent is referred to our report of the proceedings of the General Medical Council in THE LANCET of June 5th, and to numerous articles in our columns and the columns of the medical press generally upon medical aid associations. All that he urges has been said more temperately and therefore more convincingly.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 20th, 1897.

THE HOSPITALS OF THE METROPOLIS AND THEIR CLAIMS ON THE PUBLIC.

THE OLD STORY.

ONCE more it becomes our duty to lay before the readers of THE LANCET and the general public, for whose charitable consideration this Annual Special Supplement is as much prepared as it is for that of our customary professional audience, the claims of the Metropolitan Hospital Sunday Fund upon the sympathy and practical assistance of all London. Nor need the readers of this appeal consider that it is only Londoners to whom the London hospitals may fairly look for aid. Local hospitals have a right and pre-eminent claim upon local purses, but if local purses can spare a tribute to the metropolitan institutions, such help should be offered, for the London hospitals receive daily and uncomplainingly patients from all parts of the United Kingdom.

We have made this appeal for the Fund on ten previous years. Therefore, although we have approached the subject from different directions on different occasions, and have dwelt at length now on this and now on that phase in the history of hospital work in the metropolis, we feel that to many the subject has, perchance, become threadbare. It may even have lost its interest for them altogether through this familiarity, for, vary the rendering of it how we will, our main tale must always be the same. The hospitals of London do noble work; the amount of work is out of proportion to their precarious incomes; London, the city of untold wealth, should be able to furnish not only adequate but regular hospital accommodation for its suffering poor; Hospital Sunday gives the inhabitants of the metropolis and all others on whom the London hospitals have any claim, logical or sentimental, a regular and annual opportunity of showing their appreciation of the splendid work done by these charities; therefore, let all give according to his or her means.

The rich should give out of their bounty, and not only because they are rich, but because they are directly benefited by the hospitals. It must not be forgotten that many of the accidents dealt with in the emergency wards of the London hospitals have befallen the wealthy, who are exposed as much or even more than humbler citizens to the risks of the streets. The poor should give out of their poverty, and they need no reminding what the hospital means to them when they are sick. To the benevolent-minded no scheme can commend itself as more worthy of their aid than a fund to benefit their suffering and poorer brethren. Lastly, in the eyes of the practical, no less than in those of the benevolent, the Fund must find favour, for it represents order in the distribution of charity, while it strengthens the voluntary system of hospital support, of which we are all properly proud.

SPECIAL FEATURES OF THIS YEAR'S APPEAL.

In this our eleventh appeal to the charity of the public in behalf of the Metropolitan Hospital Sunday Fund, we have to take into consideration two entirely new factors that must influence the minds of contributors. The first of these is the selection by the Prince of Wales of the metropolitan hospitals as the fittest object of national munificence in commemoration of the glorious and prolonged reign of his Royal mother. Such an appeal as that made by the Prince of Wales can hardly fail in some directions to militate against the chances of the Metropolitan Hospital Sunday Fund. We do not yet know to what figure the sums given in response to this appeal will attain, so that we cannot yet estimate how far the fund may be looked upon as a stop gap only, however efficient and sorely needed, or how far it will constitute a fund the capitalisation of which will place the hospitals benefiting thereby beyond the reach of poverty—at least, so long as existing conditions hold good. But whether the appeal result in the substantial permanent benefit which we all hope it may, or only in a sum adequate to relieve the more pressing needs of the hour, it must in either case appear to the charitable public as a rival to the Metropolitan Hospital Sunday Fund, or rather as a fund which they may prefer to the Metropolitan Hospital Sunday Fund without altering the direction of their charity. Yet it is perfectly clear that it is a bounden duty, imperative upon all who can afford the dole, to support both funds, and in no way to let the older charity go to the wall because of the more special and (may we be allowed most respectfully to say?) more sensational circumstances which surround His Royal Highness's appeal.

The second factor which will for this year, and not only for this year but possibly for many years to come, be at war with the Metropolitan Hospital Sunday Fund is the feeling that is abroad that the hospitals themselves

Hosted by Google

stand in need of reform, institutional, domestic, pecuniary, and even scientific. It is sad, indeed, that any such idea should be rife, for it is based upon insufficient evidence and is the outcome of conclusions many of which are unwarranted and a few of which are absurd. That defects can be found in the management of some of our metropolitan hospitals is not to be denied; we are not even prepared to contradict the assertion that certain of these hospitals are entirely unnecessary and so form but excrescences on the tree of proper charitable endowment; but we uncompromisingly assert that, as a whole, the metropolitan hospitals are deserving of all support, and that whoever hints to the contrary is inspired by ignorance or worse. The movement for what is known as "hospital reform" is one to which we have lent support in work. On the other hand, certain long-felt and well-founded beliefs that this work is much crippled by the perpetual abuse to which the charity of the hospitals is subjected have this year found a loud voice, and the careless listener might think that institutions against which serious indictments of mismanagement were being brought had forfeited public confidence. We hope to show that there is nothing in either circumstance that should jeopardise the collection for the Metropolitan Hospital Sunday Fund for 1897. We hope to show that no one who rightly understands either the truth of the Prince's wishes or the questions included under the phrase "hospital reform" ought to allow his usual subscription to be withheld or diverted from the Metropolitan Hospital Sunday Fund.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1896.

TABLE I. — GENERAL HOSPITALS.*

N.B.—The figures referring to out-patients in these Tables represent the number of VISITS *paid by out-patients—*NOT *the* NUMBER *of out-patients.*

Name of Hospital.	Hospital Sunday Fund award.	In-patients.	Relieved.	Cured.	Convalescent homes.	Remaining under treatment.	Died.	Out-patients' visits.	Accidents and emergencies.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

THE LANCET, so that it would be pusillanimous of us to be unprepared to discuss its meaning and possible influence; but before doing so we would premise that there is nothing in the abuses to which loud attention is now being called that is either new or of a character that would warrant even the most canny among the subscribing public in drawing tight their purse-strings.

Such are the special circumstances which mark our present and eleventh appeal to the public in behalf of the Metropolitan Hospital Sunday Fund. His Royal Highness the Prince of Wales, with a sense of the fitness of things that should be an element in the character of all princes, and for the possession of which he himself is famed by universal acclamation, has made subscription to the metropolitan hospitals in this year of extraordinary jubilee an act of loyalty and fealty to the most remarkable crowned head in Europe, and his selection of the metropolitan hospitals as the vehicle by which honour may be done to our revered and beloved Sovereign is a warranty of the enormous prestige that these institutions enjoy for unselfish and noble

THE METROPOLITAN HOSPITAL SUNDAY FUND AND THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

"I am aware that the task of distributing the funds when collected will not be without its difficulties. It may be desirable in the future to seek the assistance of representatives chosen by the hospitals, but for the first year we shall rely upon the coöperation of the Distribution Committee of the Hospital Sunday Fund."—*Extract from H.R.H. the Prince of Wales's circular letter to the Press announcing the institution of his Hospital Fund for London.*

As the support of the Prince of Wales's Fund grows larger public interest in his beneficent scheme grows deeper. And this interest is of a twofold character, as we have already pointed out in THE LANCET. There is interest as to the amount of the Fund that is to signalise so great an event as the prolongation of the reign of Her Majesty to sixty years, and there is almost equal interest in the principles on which it is to be used and distributed.

It is impossible even at this very late date to form any precise conception as to the amount that will be realised by the subscriptions to the Prince of Wales's Fund. Some three weeks ago it was announced that sums had been received as donations and subscriptions, commuted or otherwise, representing an income of about £22,000 per annum; but since that date

Hosted by Google

the Jubilee Stamps have been issued, and have, we understand, met with a satisfactory sale, while every day the receipt has been advertised of large sums and small sums from all sorts and conditions of men. Hospitals, in fact, have never received subscriptions from so many individuals as they will receive through the powerful agency of His Royal Highness's Fund. The extraordinary jubilee of their venerable Queen has appealed with a commanding effect to all her people; and as a result, whatever the total of the subscriptions in answer to the Prince's appeal may amount to, there can be no doubt as to the number of subscribers.

The class from which the Prince of Wales's Fund has received support has been as varied as the sums subscribed. And this is as it should be. Primarily, the hospital is the gift of the well-to-do to the poor—of the man who, being able in his own home to obtain medical and nursing skill for himself, is desirous of providing the same medical and surgical skill for his poorer neighbour when overtaken by grave accident or disease. But secondarily the British hospital is a national institution, of which all should be proud and to which all should subscribe, for there is no country in the world that can show any institution like it for valuable and unselfish work. Do we sufficiently consider what the voluntary hospital system means, and what the community would lose by placing the hospitals upon the municipal rates, by making them depend upon subsidies enforced, for example, from public entertainments, or by quasi-exalting them into the stations of a new Government department? These, or some combination of these, are the alternatives of the voluntary system—a system of which the whole nation should be proud. The spontaneity of the large annual gifts and bequests to our hospitals stands out pre-eminent in a not unselfish age as a grand testimony to the right-thinking generosity of the wealthy, as a proof not to be gainsaid that the sympathy of the rich with the poor and of the whole with the sick is not merely of the lip, but proceeds from the heart also. Yet it would be wrong to bolster up the voluntary system, however morally splendid, if it were found to be unworkable in a practical world. Most of the hospitals are practically at their wit's end for money. Now it may be asserted: If so, the voluntary system must have broken down. The endowed charities must have lost or mis-spent their endowments, and they, together with the unendowed which have ceased to justify their existence in the eyes of the charitable, must come upon the rates. We do not think so. This is not the place to discuss the problems of State-supported hospitals and the need for a hospital board, and no attempt will be made to do so. But a few words may be said to show that in the opinion of the thoughtful the voluntary system is the best. In the year 1890 the House of Lords appointed a Special Committee to investigate the whole subject of hospital administration and accommodation in the metropolis, and that Committee, after deliberation which extended over two years, during which it received the assistance of a large number of highly competent witnesses versed in the various branches of the subject, produced a report. Although dealing with a great number of topics, this report was mainly directed towards proving how greatly the work of the hospitals would be expedited, how enormously it would be advanced by improved organisation—by a knitting together, in fact, of all the institutions into one coöperative whole; but not a word was said against the voluntary system. More order and uniformity of administration were found to be desirable under the system, but against the system itself *not a word was said.* And, indeed, the advantages of the system stare us in the face. No man can obtain appointments at our hospitals in return for services rendered other than medical; the influence of politics is unfelt in our treatment of pneumonia; and red-tape is not a ligature that is employed in our wards. If the hospitals were supported out of the rates they would be, no doubt, economically managed; for, in spite of ill reports occasionally prevalent, we are all satisfied with our municipal governments. But municipal government is not the rule that is aptest for scientific institutions. It has been abundantly proved that municipal authorities are not faultless or firm judges of medical procedure. Local influences interfere with uniformity of treatment, and are particularly pliable before the blast of vain doctrine. Experimentation in foolish methods might be made to figure as enlightened freedom from prejudice if certain of our municipalities had the right to rule our hospitals. We may consider that the Prince's appeal forms another powerful argument in favour of the voluntary system, for had he entertained any doubt upon this point, or had he been advised that there was any difference of opinion among men of experience on this point, we may be certain that provision would have been made for the answer of possible objections.

We have spoken of the vast number who will this year subscribe to the needs of the hospitals through the medium of the Prince's appeal, as well as through the Metropolitan Hospital Sunday Fund. We now have to say a few words as to the quality of the new subscribers. The Prince's scheme is bringing into the line of hospital supporters thousands, with means ample or narrow, who have hitherto not contributed—rather probably from want of thought than from want of heart. It has been always one of the mysteries in connexion with the support extended to hospitals that it has been offered by so few. It has seemed an insoluble puzzle that thousands of people who could well afford to give something should every day of their lives pass hospitals to which they never contribute a farthing, and that their consciences have never seemed to reproach them for their neglect. The Prince has brought the needs of the metropolitan hospitals home to these thoughtless ones. The daily list and the prevailing sentiment lead us to hope that by the institution of the Prince's Fund a permanent blow has been struck at this indifference, and that consequently the hospitals of London will henceforth be less straitened in their endeavours to meet the really urgent cases of the classes for whom they were intended, because they will henceforth be able to depend upon a wider sympathy.

The value of these small subscriptions from a large number of people can hardly be over-estimated. If we glance at the table below, in which is summarised the practical progress of the Metropolitan Hospital Sunday Fund, we are immediately confronted with the fact that individual generosity has played an enormous part in the collections, and that the people of London have in no way levied a voluntary rate upon themselves to support their voluntary hospitals:—

Progress of the Metropolitan Hospital Sunday Fund.

Year.	Totals.	Donations.	Year.	Totals.	Donations.
1873	£27,700	£1844	1885	£34,320	£2555 [2]

1882	34,146	2106	1894	43,679	7717 [9]
1883	33,935	1980	1895	60,361	21,990 [10]
1884	39,329	6410 [1]	1896	46,035	1672 [11]

[1] In 1884 £4500 was received from the managers of the International Health Exhibition.

[2] In 1885 a special donation of £1000 was received from Dr. James Wakley, Editor of THE LANCET.

[3] In 1886 a further special donation of £1000 was received from Dr. James Wakley.

[4] In 1887 a legacy of £1000 was paid by the executors of the late Dr. James Wakley.

[5] Including legacy of £1003 14*s.* from the executors of the late Mr. Thomas Crouch.

[6] In 1891 donations of £5000 from the late Duke of Cleveland, &c., and £1000 from Sir Savile Crossley, Bart., were received.

[7] In 1892 Sir Savile Crossley, gave a further £1000; and a legacy of £105 was paid by the executors of the late Dr. H. E. Price of Brighton.

[8] In 1893 Sir Savile Crossley gave a further donation of £1000.

[9] In 1894 a legacy of £5000 (less duty) was paid by the executors of the late Mr. W. J. Whitaker, and Sir Savile Crossley gave a further donation of £1000.

[10] In 1895 Messrs. Barnato and Friends gave a donation of £10,000; £3400 was received from the Stock Exchange through Messrs. Pym, Vaughan, and Co., and Messrs. Burdett and Harris; Lord Iveagh gave a donation of £1000; Sir Savile Crossley gave a further donation of £1000; and Mr. J. B. Robinson gave £1000.

[11] In 1896 Sir Savile Crossley gave his sixth donation of £1000, and legacies were received from Mr. John Smith of £500 and Mrs. May Evans of £172 9*s.* 4*d.*

In 1890 the individual donations only amounted to £3991 out of a total of £42,814, so that this year may be taken as marking a high level of general generosity—that is to say, a low level of special contributions. What did it amount to? The collections by offertory came to nearly £39,000, and the population of the metropolis at that time was nearly 4,200,000, so that the average contribution of every individual would amount to something *less than twopence-farthing.* For the purpose of this estimate it is assumed that only the County Council's London is interested in the hospitals of the metropolis. But that is very far from the fact. Outside the official boundary lies a densely populated zone inhabited by Londoners, although nominally appertaining to the adjacent rural districts, and

Hosted by Google

to this area are extended in no small measure the benefits of the metropolitan hospital system. Let it, however, suffice to assume, without refining upon the figures, that Londoners were in 1890 prepared to support this great charitable work—the financing of their hospitals—to the extent of an annual subscription of twopence-farthing a head, which particular annual subscription registers general generosity at full work.[1] This is by no means an unfair way of estimating the position, for although it is quite true that a charge of whatever kind distributed evenly over the entire population in proportion to the number of heads would bear very unduly upon the poor, yet if, on the other hand, the benefits conferred by hospitals are considered, it will, of course, be found that these are in a preponderating measure realised by the most numerous and least wealthy classes of the community. The families, including children, of the poor are no less dependent than the families of the rich upon medical attendance, and to a very large extent in the case of poor people this necessity is supplied by hospitals. An estimate of population, therefore, affords the best means of realising how the benefits of the hospital service are distributed, for no class is excluded from these benefits; and when it is realised that the return made in the form of the Metropolitan Hospital Sunday Fund works out at something less than twopence-farthing a head, it will, we think, be freely admitted that there is good reason for regarding it, not only as inadequate to the needs of the hospitals, but also as unworthy of the community which

contributes it. This is a view of the case which should commend itself especially to persons of moderate means. To these the Metropolitan Hospital Sunday Fund has for four and twenty years afforded a peculiarly fit opportunity of tendering support to the medical charities of London of which no real advantage has been taken. These are the people of whom we may hope that the Prince of Wales's appeal has interested them now and for the future in the principal charitable work of the kingdom. Thousands of persons in London are so situated that the subscription list with its regulation guinea is not for them. The annual collections of the Metropolitan Hospital Sunday Fund have been brought to their notice in vain. Probably (and we most heartily hope that this will be the case) the Prince of Wales's appeal will fall on more alert ears, and will bring to the aid of the hospitals the many possessors of moderate incomes who have hitherto invariably held aloof from subscribing, if they have not as rigidly abstained from seeking gratuitous medical advice. It is from this class that the donations to the Metropolitan Hospital Sunday Fund ought not to be represented by twopence-farthing. Undoubtedly the Prince of Wales's Fund should stimulate many of this enormous class to take a practical interest in the hospitals of the metropolis, which should eventuate in considerably enlarging the circle from which subscriptions may be expected to the Metropolitan Hospital Sunday Fund.

The administration of the Prince of Wales's Fund concerns those interested in the welfare of the Metropolitan Hospital Sunday Fund more deeply than does the amount to which it may attain. It would seem that the future form and use of the Fund are spoken of as if these were still matters for further consideration. If this be so there is wisdom in the want of a definite plan. Time is thus given to study public opinion and the real questions that are at stake in any movement for helping voluntary hospitals and placing them in an unassailable position in public opinion. If the voluntary system of support is satisfactory in the eyes of all who can see clearly—and this we believe—it must not be

revenues of the Metropolitan Hospital Sunday Fund should be chiefly drawn. Large contributions are the exception of course, but they bear too high a proportion to the total. The very poor have always acknowledged the claims of the hospitals upon their gratitude, and it would be a sad day when these struggling ones withdrew from the support of the Fund and left it to be carried on by the opulent few. But the many have not really supported the metropolitan hospitals. The rich have now and again made stately donations, and we are not oblivious of several instances of princely generosity that have characterised the eleemosynary record of the past year. The very poor have done their best, as is shown by the offertory returns of the Metropolitan Hospital Sunday Fund and the contents of the contribution boxes. But between the rich and the poor—particularly if we say between the very rich and the very poor—lies the enormous class of persons who could support the hospitals adequately if they would, and whose annual forgotten that inasmuch as many of our hospitals are on the verge of bankruptcy, the system must be held to having broken down to some extent, and the weak spot in the system is very obvious. The irregularity with which the impulse to give must necessarily act deprives the donations of half their value. The voluntary principle is an admirable one, but it is jealous of order or dicipline, and prefers to act locally, impulsively, and irregularly. If certain much-needed qualities could be introduced into voluntary hospitals, if they could be brought to regard each other as coöperating for charitable ends, not merely competing with each other for public subscriptions, if they could be brought to realise certain common principles of administration, a new era of prosperity might be assured to them. In almost these identical words we have on several occasions summed up certain phases in the career of the metropolitan hospitals, and we are therefore glad to believe that there will be an opportunity given to those who will have the administration

Hosted by Google

of the Prince's Fund to initiate some scheme of the nature of a Central Hospital Board.

There are in addition two or three principles which doubtless His Royal Highness and his colleagues and advisers will bear in mind. The first of these is to do nothing in promoting their own most popular Fund to damage the existing agencies by which hospitals are supported, pre-eminent among which stands the Metropolitan Hospital Sunday Fund. As will be seen by the summary given on page 1653, the Metropolitan Hospital Sunday Fund, which has now existed for a quarter of a century, has raised a very large sum of money, close upon £900,000, while its average receipts during the last decade represent the interest upon over a million of money. This means that

the Metropolitan Hospital Sunday Fund is now recognised as a permanent agent for stimulating hospital charity and wisely supervising its administration. The Prince of Wales would not, we know, desire to interfere with the ordinary subscriptions to such a fund of those whose steady benevolence has been the reliance of hospital treasurers in the past. We have heard rumours that funds are to be diverted from their ordinary channels into the Prince of Wales's Fund, to which we have to say that such action would appear to us in the light of a particularly mean proceeding, the favour of Royalty being placed above all sentiments of true charity. To give to the Prince of Wales's Fund the subscriptions usually given to the Metropolitan Hospital Sunday Fund is merely saving with one hand to be lavish with the other, and the Prince of Wales would desire no such sycophantic rejoinders to his appeal. That the Prince's Fund is in any way in opposition to the Hospital Sunday Fund is, in fact, expressly contradicted by himself in his circular letter, while the same is sufficiently clearly shown by the reliance which His Royal Highness is placing this year upon the coöperation of the Distribution Committee of the latter Fund in the extremely delicate task of distributing the proceeds of the first extraordinary appeal.

So much, then, for the supposed antagonism between the two Funds. His Royal Highness has opened up new fields of practical benevolence, and we are certain would be the first to regret that an appearance of competition should lead to any serious diminution in the subscriptions of the senior Fund. Both Funds have the same object, and it would be but a poor compliment to Prince or Queen to rob the Fund which has a history of twenty-four years' excellent utility to swell the total of the Jubilee offering. For this year, at any rate, the Prince's Fund may be looked upon as a magnificent adjunct to the Metropolitan Hospital Sunday Fund. What future years may bring forth we cannot guess. We do not know how long the distribution of the Prince's Fund will be left to the Metropolitan Hospital Sunday Fund. We do not know how far the receipts will be treated as capital to pay off the pressing liabilities of some hospitals or how far they will be invested with a view of forming a permanent income. We do not know if any attempt will be made to formulate some common scheme of use for the money, such as a Central Board would insist upon before distribution. But we are certain that it would have powerfully contributed to the success of the Prince's Fund if it had been confined and concentrated in respect of the duration of the appeal, for the continuation of it into future years must tend to detract from its success. And we are also certain that nothing can be further from His Royal Highness's wishes than to imperil the regular prospects and the established income of the older fund, and that in his eyes no gift could have any merit which had been withheld from the Metropolitan Hospital Sunday Fund to be poured into the coffers of the Jubilee appeal. Both by word and deed the Prince of Wales has disclaimed any rivalry.

THE METROPOLITAN HOSPITAL SUNDAY FUND AND THE HOSPITAL REFORM ASSOCIATION.

"We are of opinion that considerable abuse exists among these special hospitals in the following ways: (1) By the treatment, either free or for a small sum, of a patient who could afford to pay a reasonable fee outside; (2) by the admission of patients who do not actually require treatment by a specialist; and (3) by the treatment in some instances of more patients in a given time than can be considered either advisable or defensible."—*Extract from the Report of the Committee of the Hospital Reform Association on the Working of the Special Hospitals of London.*

The mere existence of a Hospital Reform Association would seem to be an argument against generosity to any fund designed to assist hospitals, and if the Metropolitan Hospital Sunday Fund were not in some senses a disciplinary body as well as a charitable body, undoubtedly the argument would be a valid one. But the care which has always been taken in the distribution of moneys received has made the Fund a practical deterrent of some forms of hospital abuse—that is, a sort of Hospital Reform Association. For the Distribution Committee of the Fund, by putting a premium upon good management and economy, and by rigidly exacting that all hospital accounts shall be rendered for their inspection in accordance with a uniform plan, stimulate the less scrupulous institutions to set themselves in order lest they should fail to obtain a grant.[2] This year those responsible for the distribution of the receipts of the Fund have had a communication made to them from the Hospital Reform Association, which previously appeared in

[2] "Your Committee have this year had occasion to question the administration of nineteen institutions. Each of these have been given the opportunity of sending a deputation in conference. Your Committee are, however, glad to report that in most cases the objections raised were frequently explained satisfactorily. There are now very few institutions which do not publish their accounts on the uniform system agreed upon. One special hospital, having no present need, gets no award. One convalescent home, where the charge for maintenance of patients was deemed excessive, has no award recommended. The managers of an institution, classed as a dispensary, were requested by your Committee to produce their minute book. This they declined to do, and your Committee being doubtful of the existence of any such book have recommended no award. The result of all their interviews will, your Committee hope, lead to improvement in the future."—*Extract from the Report of the Distribution Committee of the Metropolitan Hospital Sunday Fund for 1896.*

Hosted by Google

the columns of THE LANCET, and which can hardly fail to attract attention from them. The Hospital Reform Association appointed a committee to inquire into the working of the special hospitals in the metropolis, and it is the report of this committee to which we refer. The report was an interesting document, and showed that the newly formed Association perceived the responsible nature of the work that it had assumed. For in these critical times for hospitals it is necessary to recognise, firstly, their value, and, secondly, the danger there is of their altogether losing their original character and with it their claims as charitable institutions of the first order. The authors of the report, while ready to admit, if not the virtues of special hospitals, at least the virtues of those who represent them, pointed out in clear words the reluctance of some officials to give information as to their institutions, and published in a tabular form some statements which should either be explained or denied. Certain contradictions of these statements have reached us, but, giving them their full value, we still find that the Hospital Reform Association has justified its inquiry by demonstrating the need for further inquiry.

Looking at the financial system on which a large number of the special hospitals are worked, the Hospital Reform Association has in the report of its committee stated that many of them are largely dependent on the payments of patients. Of the forty-one special hospitals visited, at least thirty were shown to receive direct payments from their patients, the receipts from this source amounting in 1895 to £24,085, and over half of these institutions obtained more money from patients than from annual subscribers. One institution received twenty-five times as much from its patients as from its subscribers. At another it was open to the medical officers to see private patients, and it was not easy to ascertain who decided which were private and which were hospital cases. At another the income derived from patients' payments was nine times as large as that derived from annual subscriptions, and the authorities appeared by the report to be accommodating in their charges to out-patients, who may be called upon to pay on a sliding scale from 6*d.* to 10*s.*

The conclusion is irresistible that at certain of these institutions charges are made so that, while medical and surgical practice is being carried on in unfair competition with the practitioner, the institutions are losing their character as charities. As soon as a hospital begins to charge its out-patients fees, however small, it must cease to base its chief claim to help from the Metropolitan Hospital Sunday Fund upon the large number of out-patients which it treats during the year. An imposing tale of sick relieved is in such cases counterbalanced by commensurate addition to the funds of the institution, and it will behove the Distribution Committee of the Metropolitan Hospital Sunday Fund to look more closely into this matter than they have ever done. Insistance on a wage limit, with occasional departures from it at the discretion of a competent inquiry officer, might do good; the total abolition of the system of subscribers' letters would also have its advantages; while the staffs of the hospitals can do much to avert the promiscuous abuse of the charities. But we place implicit confidence in the discretion of the Distribution Committee. They can be relied upon not to shirk the difficulties of their position—if we thought otherwise we should not year by year do our utmost to swell the sum with which they will have to deal—and they can be trusted to apportion the moneys with justice.

In view of the urgent importance that the question of hospital abuse has now assumed, THE LANCET this year addressed the following question to the secretaries of all the metropolitan institutions who benefited last year by the collections of the Metropolitan Hospital Sunday Fund: "*Is it your opinion that any considerable proportion, and can you say what proportion, of hospital out-patients are in a position, were they so disposed, to obtain private medical advice?*" To this question we received 60 answers. From the general hospitals 14, from the special hospitals 22, from convalescent homes 4, and from dispensaries 20. Of the 14 replies from the general hospitals, 5 acknowledged the presence of abuse and 9 denied it. In those where it was acknowledged to be present it was stated to be "infinitesimal," "very small indeed," or "quite an insignificant number." In two of those where its presence was denied the improbability of the existence of much abuse was based upon consideration of the fact that the crowded waiting-rooms were so uncomfortable that it was unlikely that any who could afford to go to a private medical man would care to subject themselves to the inconvenience of the hospital. This we do not consider at all a good ground for doubting the presence of abuse, for it is notorious that mean people daily subject themselves to grave inconveniences to escape their just liabilities. (By the way, if these waiting-rooms are really so very uncomfortable they form no fit places wherein to receive the sick, whether worthy objects of charity or not.) Of the 22 answers from special hospitals 7 deny *in toto* that abuse takes place, while 15 admit the possibility of abuse, but in several cases qualify their admissions by saying that the abuse is "very slight," "infinitesimal," or "a decimal percentage." In more than one of these hospitals it appears that the strictest precautions are taken to prevent abuse, the out-patients being visited at their own homes to see what their real circumstances are, while strict inquiry is instituted into the means of all new patients. Of the 4 letters from convalescent homes 3 speak of the possible existence of abuse. Of the 20 letters from dispensaries, 3 deny the presence of abuse and 17 admit it, the amount being very variable. On the one hand we read of "many unfit cases," "30 per cent. of abuse," and "a large proportion able to pay"; and, on the other, we read of "only a very small percentage," or "10 per cent.," of improper cases presenting themselves, the abuse being "very small" or infinitesimal." One curious little discrepancy in the replies could not fail to attract attention. At one dispensary no patient is eligible whose means exceed £2 weekly, while at another the wage limit for a single man is fixed at £1 to avoid abuse. Here someone has blundered.

The conclusion we have come to on perusing these letters in connexion with the report of the Hospital Reform Association is that it will be imperative upon the Metropolitan Hospital Sunday Fund to use all powers of discrimination to reward only such institutions as have a perfectly clean reputation. All trading upon charity of unnecessary hospitals must be abolished. The Metropolitan Hospital Sunday Fund will this year enjoy remarkable power, because the Distribution Committee will coöperate in the administration of the Prince of Wales's Fund. Therefore, this year they will be able to discriminate in a marked manner between the deserving and the undeserving institutions. And, for our part, we heartily desire that in any doubtful case their leaning may be towards severity. For there are many hospitals in the metropolis whose truly charitable character cannot be called in question, and whose pecuniary plight is so desperate that no amount of increase that might be conceived possible to the usual grant could be considered excessive. We should regret that any injustice should be done, but it is evident that any money diverted to one of these hospitals by erroneous sternness from an equally

meritorious hospital would still remain well-directed charity; while it is equally evident that to make a grant to an undeserving hospital by error or out of abundance of funds is to misapply trust money. We have every confidence that those in authority over the Metropolitan Hospital Sunday Fund will deal fairly and thoroughly with the very difficult question of "hospital abuse."

THE METROPOLITAN HOSPITAL SUNDAY FUND IN A YEAR OF EXTRAORDINARY CHARITABLE ENTERPRISE.

It is as an economising agency that the Metropolitan Hospital Sunday Fund has achieved its greatest success. At present there is no sure prospect of the creation of any Central Board, but the Council of the Metropolitan Hospital Sunday Fund have been in a position to accomplish much, by way of suggestion and criticism, to advance the interests of coöperation among the various charities for the London sick. The Council have exercised a gentle but by no means ineffective supervision over hospital expenditure, and by comparison and scrutiny enforce the doctrine that every pound of revenue must be represented by its equivalent in the form of service or of necessaries supplied to the objects of the charity. In this way they accomplish what no private benefactor could do were he never so assiduous to the ungracious task of criticism. The Council speak with the authority of numbers and are free from the suspicion of partiality in their strictures. In this way they effect what has never before been attempted, and in a very considerable measure succeed in a task in which success, though of vast importance, is singularly difficult of attainment. Their contributions thus have a double value, aiding in the support of the assisted institutions and contributing very materially to the economy of the whole revenues from whatever source derived.

The promoters of such work as this have a right to look forward in this, a year of extraordinary charitable enterprise, to an extraordinary measure of support. But circumstances have decreed that in place of these pleasurable anticipations they should be forced to ask themselves most concernedly whether they are likely to receive as large a sum as usual. We appeal most strongly to the public—to the rich, the well-to-do, and the poor alike—to respond to the claim that is made upon their charity in behalf of the Metropolitan Hospital Sunday Fund and to immediately *now, TO-DAY*, contribute all that can be spared to a worthy object. Particularly we would beg to insist upon the fact that the Fund represents not only the purest charity, but order in that charity. It is this fact which makes us regard the organised movement against "hospital abuse" as a factor that should work for the increase rather than the decrease of the contributions to the Metropolitan Hospital Sunday Fund; for the manner in which the Fund has been hitherto administered should be a guarantee to the public that their subscriptions will be used for the alleviation of the misery of fit objects of charity only.

We desire, then, in this the year which sees the preservation of Her Majesty Queen Victoria to reign over us for the unprecedented period of sixty years, to beg of our readers and the public that the Metropolitan Hospital Fund may obtain from them unprecedented support. Do not, we implore, let the claims of this Fund be forgotten. Subscribe freely to any other object of charity that is brought to your notice as a method of commemorating the great Jubilee year; but let such subscriptions be in excess of your ordinary charity, and pay to the Metropolitan Hospital Sunday Fund at least the tribute which you have hitherto paid.

Notes on Some Recent Therapeutic Agents.

ANTI-DIPHTHERITIC SERUM, DRIED (B., W. & CO.).

It will be remembered that BURROUGHS, WELLCOME & Co. were the first to produce dry anti-diphtheritic serum of full potency. This form of antitoxin possesses conspicuous advantages. It is readily soluble in three or four parts of water; the volume of the injection is only about 1·3 c.c. for 1000 units. It enables the physician to administer serum of any desired potency. It is perfectly sterilised and keeps better than the liquid antitoxin in all climates. Each package of serum contains practical directions for use, a clinical chart, and an outfit for the transport of specimens for bacteriological diagnosis. Anti-diphtheritic Serum, Dried (B., W. & Co.), is supplied in tubes, each containing 1000 units, price 1s. per tube.

Liquid Anti-diphtheritic Serum (B., W. & Co.) is also supplied in bottles containing 1000 units at 1s. per bottle. Supplies of these serums are sent *immediately on receipt of* letter or telegram. Copies of clinical reports from the medical journals will be gladly forwarded on request.

THE B., W. & CO. SERUM SYRINGE.

This Syringe is adapted for use with all serums. It is entirely of British manufacture, excellently finished, and strong. All the parts are readily detachable and may be rendered aseptic with the greatest ease. It is more compact than those hitherto in use. By an ingenious arrangement the rubber plunger can be instantly and accurately adjusted to the calibre of the syringe barrel. The B., W. & Co. Serum Syringe is supplied in a metal case, with two platino iridium needles, and is fitted with finger-grips and with detachable flexible nozzle to prevent breakage of needles in case of any sudden movement of the patient. It is made in two sizes, to hold 5 or 10 c.c., the price of each fitted complete, in case, being 25s.

THYROID GLAND SUBSTANCE "TABLOIDS."

(1½ *grain and* 5 *grain.*)

Whilst the medical journals at home as well as in the colonies, on the continent and in America, continue to publish convincing clinical reports of the value of "Tabloids" of Thyroid Gland Substance, many physiological investigators who have used the so-called "extracts" have had to face failure and disappointment. In some cases untoward clinical results have even been attributed to the system of treatment, while the fault has lain with the imperfect preparation of the gland used.

It is obvious that extracts are very liable to represent only a portion of the active constituents of the thyroid gland, and necessarily vary in activity and constancy.

"Tabloids," on the other hand, represent the *whole* active substance of the gland. Their method of preparation ensures that the glands are carefully selected and free from disease Many thousands are worked in batches and brought to a homogeneous mass, and an average percentage of the active constituent is obtained. The dose can thus be regulated with the utmost certainty.

At the last meeting of the British Medical Association papers were read on the action of Thyroid Gland Substance in sarcoma, uterine fibroids, mental diseases, exophthalmic goitre, sporadic cretinism, and imbecility in children. Many reports on the therapeutic value of Thyroid Gland "Tabloids," and on their freedom from causing thyroidism, have since appeared, copies of which with samples will be posted to medical men on request.

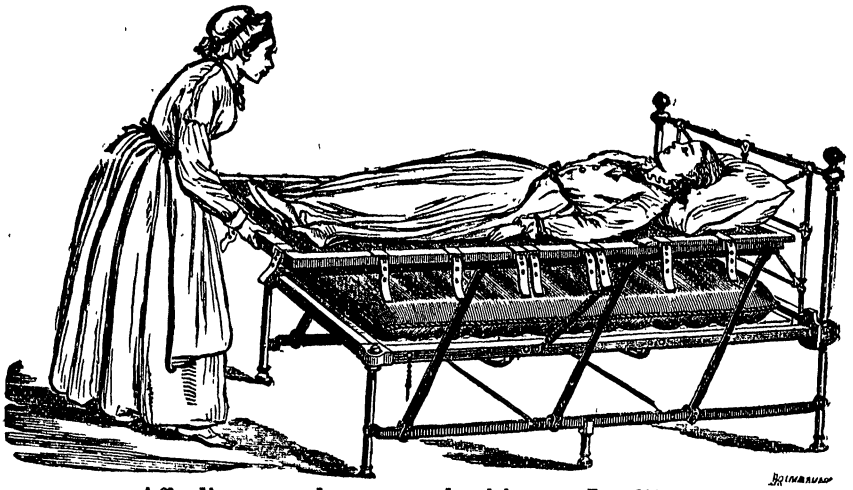
Thyroid Gland Substance "Tabloids" are supplied in bottles of 100 (1½ grains) at 10d. per bottle, and 100 (5 grains) at 2s. per bottle.

BURROUGHS, WELLCOME & CO.,
LONDON AND SYDNEY.

Cable and Telegraphic Address—"BURCOME, LONDON."

'Emol-Keleet'

A natural powder containing a large proportion of native silicates, employed as a diluent for such potent therapeutic agents as Loretin, Iodoform, Dermatol, Boric Acid, etc., and as a drying and dusting powder.



Its soft, silky texture, soothing influence, and other valuable qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other powders have failed.

Supplied in tins at 9d. each.

The Croonian Lectures

ON

THE MEANS BY WHICH THE TEMPERATURE OF THE BODY IS MAINTAINED IN HEALTH AND DISEASE,

Delivered before the Royal College of Physicians of London,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, GUY'S HOSPITAL.

LECTURE I.[1]

Delivered on June 15th.

MR. PRESIDENT AND GENTLEMEN,—In the first place I have to express my very best thanks for the great honour which our late President, Sir Russell Reynolds, conferred upon me when he invited me to deliver the Croonian Lectures before this College. After I had said I would deliver them I looked down the list of my predecessors, and since I saw how distinguished a list it is I have often regretted my boldness, and I can assure my hearers that no one is more fully aware than I am of the many deficiencies in the lectures I am about to give.

I propose in them to discuss the details of the means by which the temperature of the body is maintained in health and disease. My hearers will find that many points are omitted, but when they call to mind the great complexity of the subject and the scantiness of our knowledge they will, I am sure, forgive me.

I have purposely avoided the word "fever" in the title of these lectures, for it lacks exactitude. It is an admirable word, but it has been handed down from a time when less was known than we know now and when the clinical thermometer was not employed. As we use it to-day it is difficult to define in such a way as to cover every use of it, but probably most of us mean by it to designate a certain assemblage of symptoms which follow the introduction into the body of certain poisons; thus, when an unprotected person is inoculated with small-pox he shows certain symptoms, and is therefore said to have a fever. One of the most prominent of these is pyrexia, but pyrexia may occur, as I shall show, if we remain a long while in a hot bath or as a result of cerebral hæmorrhage. Probably there are some of us who would not consider the man who had had a very hot bath or the man who had a cerebral hæmorrhage to be suffering from fever, but a study of the raised temperature in these conditions will help us to understand the pyrexia which occurs in cases to which everyone is agreed the term "fever" may be applied. Another reason for confining ourselves in these lectures to pyrexia rather than fever is that this term comprehends so many symptoms—e.g., rapid pulse and rapid respiration—that we should not have time to consider them all.

Before studying pyrexia experimentally there are some pitfalls of which we must beware. In the first place, the normal range of temperature in the lower animals is wider than in man. I have very often taken the rectal temperature of rabbits, dogs, and monkeys, and in these animals the range is greater than in man. I have compiled from Dr. Pembrey's article on Animal Heat in Professor Schäfer's forthcoming "Physiology" the appended table (Table I.), which shows very well the range of temperature in different animals.

In the next place the prolonged administration of an anæsthetic causes a fall of temperature. Thus, Pembrey[2] has proved that the temperature falls in anæsthetised mice, and Binz,[3] quoting from Kappeler, says that after the administration of ether to human beings the bodily temperature sinks from 0·3° to 1·5° C. (the mean of twenty etherisations was 0·68° C.); but it rises again in a few hours to normal. Twenty-three observations were made on the effect of chloroform on human beings, and it was found that on the average the temperature fell 0·53° C. The fall did not begin till at least twenty minutes after commencing inhalation and was generally most marked after narcosis had passed off. In from twenty minutes to five hours the normal temperature was regained. Binz, quoting from Scheinesson, says that anæsthetics do not increase the dissipation of heat, and he considers that they directly diminish the power of the body to produce heat. But in rabbits at least I can, from personal observation, state that if the anæsthetic is only given for two or three minutes no appreciable alteration of temperature takes place.

TABLE I.

Animal.	Average rectal temperature.	Extremes of observations.	Number of observations.
	Degrees C.	Degrees C.	
Horse	37·8	36·1—38·6	982
Cow	38·7	37·5—39·4	116
Sheep	40·4	38·5—41·8	304
Dog	39·0	37·1—39·9	250
Cat	38·7	37·9—39·7	41
Pig	39·2	38·7—40·8	269
Rabbit	38·9	37·0—40·8	110
Guinea-pig	37·9	37·0—39·2	19
Rat	37·5	37·0—38·5	16
Mouse	37·4	37·1—38·6	27
Monkey (Rhesus) ...	38·4	36·9—39·7	22

Another fallacy to be avoided in the experimental study of pyrexia is that the performance of artificial respiration will by itself cause a considerable alteration of temperature. This is particularly unfortunate, for at first sight it seems as though we might learn much about pyrexia from a study of the behaviour of the temperature when the spinal cord is cut or curare has been given; but as in either case artificial respiration would be necessary these modes of experiment are closed to us. Le Gallois[4] as long ago as 1817 showed that artificial respiration depressed the temperature, and also that to a less extent anything—such as tying an animal down—which hindered respiration caused the temperature to fall. Dr. Fawcett and I in the course of some experiments we were conducting on the physiological action of β-tetrahydronapthylamine made some observations upon the combined effect upon the temperature of etherisation and artificial respiration. Rabbits were used, the animal was kept fully under ether for two hours, and during this time it was fixed to a board in the usual way, and artificial respiration was carried on through an opening in the trachea. The following table (Table II.) shows the results we obtained.

TABLE II.

Number of experiment.	Fall of temperature.	Hours during which it fell.	Remarks.
	Degrees C.		
1	4·8	3¾ hours.	
2	2·2	2¾ ,,	These two animals were wrapped in cotton-wool.
3	3·4	3¾ ,,	

It will be seen that the depression of temperature was very considerable and that it could not be prevented by wrapping the animal in cotton-wool. It is clear, therefore, that as the combined influence of ether, artificial respiration, and fixing a rabbit to a board produces such a marked fall in the animal's temperature, this method of experiment is quite inapplicable for working out problems dealing with the variations of temperature of rabbits. We may now leave the fallacies and pass on to the chief subject of these lectures.

The fundamental problem in a study of pyrexia is to discover whether or not the production of heat is increased, for it is clear that the temperature of the body may rise either because the loss of heat from it is less, while the

[1] Lecture II. was delivered on June 17th, and Lectures III. and IV. will be delivered on June 24th and 29th respectively.

Hosted by Google

production remains the same, or because the loss of heat remains the same while the production of heat is increased, or, if both vary, because the variations in the production have not been exactly counterbalanced by variations in the loss. The opinion of the profession upon the question whether in fever the rise of temperature is due to a diminution of the loss of heat or an increase of production has varied in accordance with the views of our most distinguished pathologists. Thus Traube taught that the rise of temperature in fever is due to a contraction of the superficial arterioles, there being then less blood in the skin, the body consequently loses less heat by radiation and conduction and hence its temperature rises. Liebermeister, on the other hand, taught that the increased temperature in fever was due to a greater production of heat. But it appears to me to be possible that the discussion has in a sense been beside the mark, for we know that most, if not all, fevers are due to the circulation of poisons in the blood and there is no reason why we should believe that they all produce pyrexia in the same way. All collateral evidence is against such a view; many poisons accelerate the beat of the heart, but some act upon the vagus, others upon the accelerator nerves; many poisons produce diaphoresis, but jaborandi acts upon the peripheral terminations of the sudoriparous nerves while opium acts centrally. And I hope I shall, in these lectures, be able to bring forward evidence to show that sometimes pyrexia is due to an increased production of heat and sometimes to a diminution of the loss. If this can be done it will put an end to the discussion as to whether in fever the production of heat is increased or the loss diminished; but we shall have to discuss the question for each separate febrile disease.

Before however, doing this I should like to call attention to a point that I have never seen discussed—namely, whether there is any evidence that pyrexia may be due to a variation in the specific heat of the body. It takes more heat units to warm to a given temperature a body with a high specific heat than it does to warm a body with a low specific heat to the same temperature, so that if the specific heat of the human body diminished while its production and loss of heat remained the same its temperature would rise; and at first sight it appears that this would be a most economical way of raising the temperature, as there would be no extra expenditure of energy in increasing the production of heat; but perhaps the alteration of the specific heat of the body might entail such considerable molecular change that it would necessitate an expenditure of energy. Most observers have estimated the specific heat of the body by calculation after death from that of the various tissues of the body. The lowest estimate given by this method is 0·75, the highest 0·9; but this is what might have been expected when we remember that a large proportion of the body is water. The properties of dead and living bodies are so unlike, and the specific heat of complex substances is often so difficult to foretell, that I thought it would be worth while to see if some means could be devised of estimating the specific heat of living animals. This would be easy enough in the case of cold blooded animals by observing the relative number of degrees of temperature through which the animal and an equal weight of distilled water originally at the same temperature rose or fell when both were, under exactly similar conditions, subjected to warming or cooling, for it is well known that the temperature of cold blooded animals rises and falls with that of their surrounding medium. But the thermic mechanism of warm- and cold-blooded animals is so different that it would be rash to assume that the specific heat of warm-blooded animals is the same as that of cold-blooded animals.

It struck me, however, that by using hybernating mammals it would be possible to calculate the specific heat of living animals not far removed from man. I employed dormice, for they are easy to obtain and to observe. When hybernating they lie tightly curled up in a ball, with their feet tucked away in the centre of the ball, and it is easy to take their temperature by placing the bulb of a thermometer in the centre of the ball. The first point to determine was whether when they are hybernating their temperature rises and falls with that of the surrounding medium. The figures given in Tables III. and IV. show that it does. For example, it will be seen in Table III. that when the temperature of the room was 37° F. that of the dormouse was 37·5°, and that when it was brought into a room at 52° its temperature slowly rose till it was 49·25°; it was then put back into the cold room and its temperature slowly fell. A large number of observations gave similar results; but the experiment requires to be made with considerable care for many reasons, each of which will be found in a paper which I published.[5]

The method of experimenting was as follows. The hybernating dormouse was carefully weighed. It was then placed on the bottom of a thermometer stand, exactly like an ordinary test-tube stand in which the test-tube stands mouth upwards, except that the holes were only large enough to take a thermometer. The bulb of a thermometer was left buried in the centre of the ball formed by the hybernating dormouse. A number of cubic centimetres of distilled water equal to the weight of the dormouse in grammes were then measured into a very thin, bright, platinum vessel, which had been made to hold just about the right amount. This vessel with its contained water was placed on the bottom of the test-tube stand as far removed from the dormouse as possible. A thermometer was placed in it. The temperature of the surrounding air close to the thermometer stand was observed. All three thermometers had been tested beforehand to see that they gave similar readings. Sufficient time was allowed for all three thermometers to become

[5] Journal of Physiology, Supplementary Number, 1892.

Hosted by Google

steady. The thermometer stand with the dormouse and the water on it were then taken into a room of a temperature about 50° F., and the readings given by the thermometer which was buried in the dormouse and by that in the water were noted from time to time. When that of the dormouse was about 50° F. the thermometer stand was moved back into the cold room and the readings were again noted. It is clear that as the temperature of the dormouse rose and fell with that of the air, the number of degrees an equal weight of distilled water rose or fell divided by the number of degrees the temperature of the dormouse rose or fell in the same time will give the specific heat of the dormouse. I performed many experiments and found that, calculated in this way, the specific heat of the dormouse varies between 0 812 and 1·18, so that if we set it down at 0 95 we shall probably be very near the mark. It is noteworthy that when the thermometer stand was first brought into a warm room the earlier observations always gave a slightly lower specific heat for the dormouse than the later ones, because at first the rise of the temperature of the animal was, in comparison with the rise of that of the water, slightly the faster. The consequent slight increase in the creature's specific heat was often uniform. Thus in Table IV. the first observation gave a specific heat of 0 857; according to the second it was 0·917; according to the third it was 0 933; and according to the fourth it was 1·0. Another noteworthy fact is that if the specific heat was calculated from observations made when the thermometer stand had been removed from a warm room into a cold one, it was always slightly higher than if calculated from observations made when the stand was brought from a cold into a warm room, and also the earlier observations gave the lower specific heat.

The close agreement of these results with those obtained by calculation from the dead tissues shows, I think, that we may safely put down the specific heat of dormice as being slightly below that of water. There are in these experiments several possible fallacies, but I think I have shown in the paper referred to that they are unimportant. Because of these unavoidable fallacies the specific heat obtained by this method is only approximately accurate, but reference to the paper just mentioned will show that the fallacies lead to only a slight error, and that on the whole the specific heat calculated by this method is slightly too low. Probably the results are more accurate than those obtained by calculating the specific heat of each of the tissues of the dead body and from these results estimating the specific heat of the body as a whole. It will be observed that the figures obtained by the two methods are in close accord, but that by the method here given the specific heat appears higher than when calculated from the dead tissues.

I should not have introduced these figures had I not wished to show that whether we calculate from dead or living tissues the specific heat of the body is high, and it is obviously an advantage for warm-blooded animals, having, as they have, to maintain a constant temperature, to have a high specific heat, for bodies with a low specific heat cool much more readily when the temperature of the surrounding medium falls than do those with a high specific heat; and although it would be unfair to definitely apply results obtained from hybernating dormice to a man suffering from fever, I think we may say that at present there is no evidence that in man the rise of temperature is due to a diminution of the specific heat of the body, as whatever the temperature of these dormice their specific heat varied very little, for reference to the paper from which I have quoted will show that experiments conducted for the same time usually gave nearly the same specific heat. Further, there is no reason to believe that the human body disobeys the law that the specific heat increases with the temperature and therefore until the contrary is proved we must suppose that, other things being equal, it takes a few more calories of heat, and therefore requires a greater production of heat to raise the temperature of the body from 104° to 105° than it did to raise it from 98° to 99°.

We now pass on to a consideration of the question whether or not in pyrexia the production of heat is increased or the loss diminished. There are three ways by which this may be investigated:—(1) By comparison of the variations in the loss of heat with the variations of internal temperature; (2) by calorimetry; and (3) by chemical means; and it will be convenient if we consider them in this order.

1. Comparison of the Variations of the Loss of Heat with Variations of Internal Temperature.

The communication which Dr. Waller made to the Physiological Society on Nov. 11th, 1893, suggests the possibility of easily finding out whether in man the production of heat is increased when the temperature is raised, and of studying in detail the means employed to keep the temperature constant in health. It is clear that when the surface temperature of the body rises the loss of heat by radiation and conduction will be increased, and that when the amount of sweat secreted is increased the loss of heat from evaporation is increased, so that if in any case it can be shown that the internal temperature has risen, and at the same time the surface temperature has risen and the amount of sweat secreted has increased, the production of heat must have increased, provided that the temperature of the surrounding air is constant, and in the wards of a hospital it is kept nearly so. I will now describe the means I have employed to obtain these data.

The internal temperature.—This is taken with an accurate self-registering clinical thermometer. When only slight variations are expected it should be taken in the rectum or the axilla, for the rapidity of respiration and the temperature of the respired air affect the mouth; but when, as in many cases of fever, the temperature is raised several degrees above normal, an observation taken in the mouth will suffice, and if the observer is single-handed it is a great convenience to take it in the mouth, for the internal temperature, that of the surface, and the amount of sweat secreted should all be observed simultaneously.

The surface temperature.—This should be taken with a flat-bulbed thermometer held gently on the skin until the index is stationary; if it be held too firmly the pressure exercised will send up the mercury. Suitable thermometers can be obtained from A. Deane, of Hatton-garden. The skin of the abdomen near the umbilicus is the best place to take the temperature, for whether the person observed have his clothes on, or whether he be in bed, the skin here is less liable than that elsewhere to transient variations of temperature from exposure to currents of air. The temperature registered by the thermometer does not represent that of the skin with absolute accuracy, for part of the bulb is exposed to the air, and the skin covered by the bulb slowly gets warmed because the bulb protects it, but as my object has always been to obtain comparative, not absolute, results these errors are of no importance. The following observation demonstrates very well that these thermometers readily show variations of surface temperature. I exposed the extensor surface of my forearm for some hours to the sun, the vessels consequently dilated, and the part was red, the surface thermometer showed the temperature at a spot well inside the margin of the red area to be 34 25° C., one-third of an inch outside the margin—the vascular dilatation here being just visible—it was 33 25°; and some distance from the red patch the temperature was 32·5°. I have tried this experiment several times and the differences are always well shown. It is of interest to observe that even extreme vascular dilatation quite as great as is observed in any fever, only increased the surface temperature of the skin 1 75° C.

The estimation of the sweat.—This was estimated by using calcium chloride as an absorbent. It was fused into the bottom of a shallow circular glass box. All the boxes used in the observations had air-tight lids, and the inside diameter of all was the same—viz., 4·5 c.m.—and therefore the area of the bottom of each box was 15·9 square c.m. The inside depth was about 2 c.m. The best way to make the calcium chloride adhere to the glass is to take fine pieces of it, place them in the bottom of the box, and then add a trace of absolute alcohol. The box is then put into an oven, which is slowly heated so that in an hour it is 150° C., and then the oven is left to slowly cool again. The absolute alcohol contains minute traces of water, and this is just sufficient to soften the edges of the pieces of calcium chloride enough to agglutinate them, and this water is driven off by the heat; the alcohol, too, acts as a slight solvent. When a reading is taken the box is held inverted on the skin for a given time (in the observations I have made I have, except in a few preliminary cases, always held it for ten minutes) and the difference in its weight before and after gives the amount of sweat secreted. It is best held with one finger so that the heat of the hand shall not affect it. To obtain accurate results the boxes must not be weighed directly after they are removed from the skin, for the glass has been

Hosted by Google

warmed by the skin, consequently it displaces more air and warm air currents proceed from it while it is on the pan of the balance, and I always found that as it cools its weight slowly increases.

The following figures, Table V., show this. I tightly held

TABLE V.

Weight of box and lid before box was put in the palm	75·4593 grms.
Weight of box and lid directly after box was taken off at 9.45 P.M.	75·4625 ,,
Gain	0·0032 grms.
Weight at 10 15 P.M.	75·4644 grms.
Weight at 10.45 P.M.	75·4652 ,,
Weight at 11.30 P.M.	75·4658 ,,
Weight at 11.45 P.M.	75·4658 ,,
Total Gain	0·0065 grms.

the box with its lid off inverted on the palm of one hand, pressing it down with the palm of the other for five minutes, so that it was completely shut up in the clasped hands. Directly the five minutes was up the air-tight lid was put on the box. This table shows that the amount of sweat secreted from the palm in five minutes really was 6·5 milligrammes, not 3·2 milligrammes, as a reading taken at once would appear to show, and the weight of the box and lid did not become constant until more than an hour had elapsed from the removal of the box from the hand. But this was an extreme experiment, the box was warmed considerably by being grasped in the closed hands. When it is held on with one finger the weight becomes constant in half an hour, and probably often in less. The following figures show this (see Table VI.):

TABLE VI.

Weight of box and lid before box was put on the palm	81·6438 grms.
Weight of box and lid directly after it was taken off, 10 P.M.	81·6482 ,,
Gain	0·0044 grms.
Weight at 10 30 P.M.	81·6499 ,,
Weight at 11 P.M.	81·6499 ,,
Total gain	0·0061 grms.

Here an immediate weighing appeared to show a gain of only 4·4 milligrammes, but the gain really was 6·1 milligrammes. Therefore it is clear that to get accurate results the boxes must not be weighed till some little time after they are removed from the body. When the box is weighed before the observation it contains air at the temperature of the room, but when it is inverted over the skin it contains warm rarified lighter air, and as the box itself is warm after it is taken off the skin the air in it when the lid is put on is still rarified, and when it is weighed as the cover is air-tight it still contains lighter air than it did before the experiment began. To show this I just lifted the lid and instantly closed it again, when after an experiment the box had been left till its weight was constant. For example, in the last experiment detailed the box weighed 81·6499 grammes. The lid was lifted and immediately closed again; the box then weighed 81·6501 grammes, a gain of 0·2 milligramme. As other experiments also showed that the gain was only 0·1 or 0·2 milligramme it is clear that no account need be taken of this varying density of the air, especially as some of this gain that is only shown in the fourth place of decimals may be due to absorption of moisture from the air let in.

Another possible source of error is the condensation of moisture on the boxes; but the amount in the air in a room does not vary much in three quarters of an hour, and the box was not weighed after an observation until its temperature had become the same as it was when it was weighed before the experiment, so that this source of error is not important. It can, however, always be avoided by having in one pan of the balance a dummy empty box exactly like the one used for experiment, and weighing one against the other both before and after the observation and noting the excess of the difference between the weights of each box. It would probably not be desirable to invert the empty dummy box on the skin at the same time as the box containing calcium chloride and leave both boxes on for the same length of time close to one another, and then to weigh them one against the other immediately after; for though they would both have been warmed by the skin, yet we have seen that the error due to this warming of the boxes may be so considerable that if the two boxes had not taken up equal amounts of heat from the skin the result of observing the alteration of the difference in their weights would not be trustworthy, and it is unlikely that they would have taken up equal amounts, for one box has calcium chloride in it and the other has not, and the amount of glass in the boxes is variable. But whether the method of dummy boxes be adopted or that, which is probably more accurate, of leaving an air-tight box to cool, an air-tight lid is a necessity; for if it is not used the results will be inaccurate, because the calcium chloride will absorb moisture during each weighing, and also if no lid is used the observation must be carried on directly opposite the balance, and immediately after the box is weighed it must be put on the skin, and immediately after it is taken off it must be again weighed, but in clinical work the balance can hardly be carried to the bedside of each patient. The lids of the boxes I used fitted on like a cap, and where the lid came in contact with the box the glass of each was finely ground; if then the merest trace of vaseline was put on the ground glass the boxes became quite air-tight enough. This I proved over and over again by leaving the boxes with calcium chloride in them but with the lids on about the laboratory, and weighing them at intervals of some hours. For instance, six such boxes were left in the laboratory for twenty-six hours during which the air happened to be nearly saturated. The gains in weight are shown in Table VII.

TABLE VII.

Box 1	gained	0·0001	grm.	in twenty-six hours.
,, 2	,,	0·0002	,,	,, ,,
,, 3	,,	0·0003	,,	,, ,,
,, 4	,,	0·0006	,,	,, ,,
,, 5	,,	0·0008	,,	,, ,,
,, 6	,,	0·0010	,,	,, ,,

On another occasion two boxes gained in weight in twenty-six hours 0·1 and 0·2 milligrammes respectively. It is clear, therefore, that if the boxes are weighed within an hour or two of an observation there is no appreciable error due to absorption of moisture from the air. In the next lecture we will consider some examples of this method.

An Address

ON

PELVIC HÆMATOCELE CONSIDERED FROM THE MODERN STANDPOINT.

Delivered before the Nottingham Medico-Chirurgical Society on Friday, March 26th, 1897,

BY CHAS. J. CULLINGWORTH, M.D. DURH., F.R.C.P. LOND.,

PRESIDENT OF THE OBSTETRICAL SOCIETY OF LONDON; OBSTETRIC PHYSICIAN AND LECTURER ON MIDWIFERY AND THE DISEASES OF WOMEN AT ST. THOMAS'S HOSPITAL, ETC.

GENTLEMEN,—I feel it an honour to have been invited to address you this evening. Being but a comparatively recent importation into the medical life of London, my sympathies remain largely provincial, and I appreciate any compliment from my provincial friends with the peculiar heartiness that springs from old association and from an intimate knowledge of the debt that the profession owes to a multitude of earnest workers and close thinkers in the great provincial towns. Amongst these, Nottingham, in regard to the solidity and importance of its recent contributions to medical knowledge, occupies a conspicuous place. I allude especially to the valuable researches lately published by your president—researches that have made his name familiar to all who are interested in the advance of medical science. In my own department Nottingham is well known as belonging to the more active

Hosted by Google

and advanced school of gynæcology, and in selecting a subject for my address I have had this fact in mind. I have come prepared, not to deliver a clinical lecture, but to compare experiences with those who are working in the same field, so that we may, if possible, assist one another in the simplification of what has long been regarded as a difficult and complicated problem.

Most of you will remember the feeling of despair with which one arose from the perusal of the chapter on pelvic hæmatocele in one's text-book. The account of its etiology failed to carry conviction. Even what seemed to be definite had an air of speculation and of armchair pathology, and the acknowledged rarity of most of the conditions assigned as causes of hæmatocele did not fit in with our knowledge of its frequency. Even Bernutz, with his admirable series of well-recorded cases and observations of post-mortem appearances, was tempted to build up a theory which would not bear criticism. I allude more especially to his views on menstrual regurgitation as the most common cause of hæmatocele. The history of our knowledge of pelvic hæmatocele has, however, been so recently and so well given in the article on Hæmatocele in Allbutt and Playfair's System of Gynæcology, that I will not occupy your time by further allusion to it beyond paying to Lawson Tait the tribute that is undoubtedly his due, of having been the first to sweep away the existing confusion and, by showing the true cause of the vast majority of pelvic hæmatoceles, to simplify the subject and to give this affection its proper place in pelvic pathology.

In speaking of pelvic hæmatocele I speak of an intra-peritoneal effusion of blood in the pelvis, usually situated behind the uterus and displacing it, and limited towards the general cavity of the peritoneum by encapsulation or adhesions. I do not include unlimited effusions of blood into the peritoneal cavity on the one hand, or effusions of blood in the connective tissue of the broad ligament on the other. Neither of these should in my opinion be called hæmatoceles; the former are simply free intra-peritoneal hæmorrhages; the latter pelvic or intra-ligamentous hæmatomata. It may be that in the near future it will be convenient to describe them in the same chapter, as being for the most part due to causes which are closely allied, if not absolutely identical, and as representing merely accidental differences of site and extent. But at present, at any rate, it is usual to think of them and to deal with them separately.

Taking, then, pelvic hæmatocele in the restricted sense I have just explained, it is now pretty generally agreed that in at least nineteen cases out of every twenty the effusion, when not traumatic in its origin, is in one way or another the result of tubal gestation. In the article to which I just now alluded the writer has expressed his personal dissent from this view. It is to be observed, however, that the value of the article is mainly historical, the writer's position as a non-operating gynæcologist depriving his opinion on points of pelvic pathology of the weight that might have attached to it had he not thus been debarred from frequent opportunities of seeing for himself the condition of the parts implicated. Clinical observation, taken alone, is an unsafe guide in regard to the diseases of the female pelvis. In no department of medicine is it more necessary that close clinical observation should be supplemented by actual inspection in the operating and post-mortem rooms. Without such inspection the clinical observer can but make shrewd guesses at the true interpretation of what he sees and hears and feels. In many instances he has landed himself in a region of pure conjecture. The gynæcological manuals are, or were until recently, full to overflowing of theories dressed up in the guise of recognised facts. I could mention several pelvic ailments that have practically disappeared from the modern gynæcologists' nosology owing to the gradual recognition of the lessons learnt in the operating and post-mortem rooms.

In considering the relationship of pelvic hæmatocele to tubal gestation it is necessary to bear in mind the unfavourable conditions under which the ovum is placed when, instead of passing on, as it normally should, into the cavity of the uterus it is detained in the Fallopian tube. The surroundings of the ovum under such circumstances are ill-adapted for the function they are called upon to fulfil. The walls of the Fallopian tube have no such rich blood-supply as those of the uterus. The result is that the ovum fails to obtain the nourishment necessary for its satisfactory development. There is a certain increase in the number and in the size of the tubal vessels, but in spite of this the vascular connexions between the ovum and the maternal tissues are always more or less insufficient. Hence, no doubt, the frequency with which the embryo meets with an early death in cases of tubal gestation, and hence also the liability to hæmorrhages in and around the membranes and to the formation of tubal moles. But it is not the vascular supply alone that is unsuited for the wants of a developing ovum, the mucous membrane and muscular coat of the tube wall are equally so. There is no properly constituted decidua to contribute to the formation of the placenta and give it firmness of attachment and definiteness of outline, and the muscular coats in the tube-wall, instead of responding to the stimulus of pregnancy and undergoing the remarkable development and hypertrophy that the uterine muscle undergoes in normal pregnancy, becomes thinner and thinner, until, under the influence of some slight effort, the tube-wall gives way, the site of the rupture being the spot where the penetration of the chorionic villi has made it especially weak. I am not professing to give an account of tubal gestation, and therefore will not enlarge upon these points. At the same time, it seemed desirable to call to mind the anatomical reasons for the well-recognised instability of the fecundated ovum when it has accidentally failed to reach the uterus, its proper home. The phenomena which lead to and accompany tubal rupture are now well known. The tube-wall, becoming more and more thin as it becomes more distended by the growing ovum, is often stretched still further by the occurrence of an intra-tubal hæmorrhage. Such a hæmorrhage may of itself be sufficient to cause rupture by occasioning a sudden increase in bulk of the contents of the gravid tube; if not, a slight additional shock or strain will be all that is now necessary to produce it. The accident occurs usually between the fourth and the twelfth week. Sometimes only a small rent takes place at first, to be followed by an extension of the tear some hours or days later. We are all familiar with the diagrams illustrating the two great varieties of tubal rupture. In the one the rent occurs in that part of the circumference of the tube where there is a covering of peritoneum. The hæmorrhage in this case takes place into the peritoneal cavity. If the ovum itself or any part of it escapes through the rent along with the stream of blood, this extrusion is necessarily also into the cavity of the peritoneum. In the other and much less frequent variety the rent is situated in the inferior portion of the tube—that, namely, which is uncovered by peritoneum, in which case the extrusion of the ovum and the hæmorrhage take place into the connective-tissue between the two peritoneal coverings of the broad ligament. This is known as intra-ligamentous or extra-peritoneal rupture, and the swelling in the broad ligament occasioned by the extravasated blood is known as hæmatoma of the broad ligament. Some writers, unfortunately in my opinion, speak of it as extra-peritoneal hæmatocele. The subsequent fate of the ovum, when it has thus escaped whole or in part into the mesosalpinx, need not now detain us. It is only necessary to remind you that a secondary rupture into the peritoneal cavity may take place subsequently, the products of conception and accompanying extravasation of blood escaping through a rent in the peritoneal covering of the broad ligament. Whether the blood, poured out into the peritoneal cavity by primary rupture into that cavity as in the first variety, or by secondary rupture, as in the second variety, forms an intraperitoneal hæmatocele, or remains free in the peritoneal cavity without encapsulation, depends chiefly on the extent of the hæmorrhage and the rapidity with which the blood is poured out. In other words, it depends on the number and size of the torn bloodvessels. If the hæmorrhage is considerable and takes place rapidly, as is the case where one or more large vessels are torn, there is not time for the blood to accumulate in the pelvis and surround itself with a roof of adherent viscera or a capsule of coagulated fibrin. The blood escapes into the general peritoneal cavity and remains diffused amongst the abdominal viscera. I shall show presently that this is what occurs in by far the majority of cases of intra-peritoneal rupture of a tubal pregnancy.

I now pass to the consideration of another group of cases, in which, owing to the causes I have already enumerated, one or more hæmorrhages occur between and around the coverings of the ovum, but in which rupture does not take place. This occurrence is described by some writers as the formation of a tubal mole, by others as apoplexy of the ovum. The usual result is that the embryo is destroyed by

Hosted by Google

the pressure and that the amniotic sac is flattened and compressed against the wall of the tube by the intra-tubal blood clot. Mr. Bland Sutton has shown that in most cases of tubal gestation the abdominal ostium of the pregnant tube becomes occluded from the sixth to the eighth week. Up to the sixth week it is open—often, indeed, unusually patulous. It is clear that so long as the abdominal ostium of the tube remains open—i.e., up to about the sixth week in the majority of cases—it is possible for the blood poured out into the interior of the tube to escape through its open mouth into the peritoneal cavity. It is also clear that the ovum itself, or a portion of it, may be expelled from the interior of the tube into the peritoneal cavity by the same route—that is, through the still open free end of the tube—without rupture of the tube itself. Such an occurrence is called a tubal abortion. Mr. Lawson Tait dislikes the expression as suggesting analogies which do not exist; but it is a useful term, and as it has met with general acceptance it would be pedantic in me to ignore it. Where the entire ovum thus escapes the abortion is said to be complete. Where the embryo alone escapes, the remainder of the ovum still lying within the tube, the abortion is said to be incomplete. Where there is simply hæmorrhage from the open mouth of the tube, without the escape of the ovum or of any part of it, there may be said to be a threatened tubal abortion, though I think the better name is the more lengthy one of "hæmorrhage from the open end of a pregnant Fallopian tube." As a rule such hæmorrhage is not excessive in its amount or poured out in a rapid stream; it is most frequently a continued trickle. The conditions, then, are those which I have already described as being favourable to the encapsulation of the effused blood—that is, to the formation of a pelvic hæmatocele. In rare cases the hæmorrhage occurs too rapidly and in too great abundance for this to take place; and then we have, as the result of this bleeding from the open mouth of the gravid tube, a free effusion of blood amongst the abdominal viscera in the general peritoneal cavity. My chief object is to bring forward some rather striking evidence in favour of the view that pelvic hæmatocele is not usually the result of the rupture of a tubal gestation, as is commonly stated in the text-books, but that it is far more commonly the result of the hæmorrhage I have just described as taking place from the open abdominal ostium of a pregnant but unruptured tube, and that it is only in very exceptional cases of rupture that the blood is poured out in sufficiently small amount and with the requisite deliberation to result in the formation of a hæmatocele. The distinction is more than an academical one; it necessarily influences our views as to treatment. But before giving the figures from my own practice I must allude for a moment to the condition known as hæmatosalpinx, and show what relation this condition bears to the phenomena I have just been describing. Hæmatosalpinx is the name given to an effusion of blood within the Fallopian tube. It is now known that the majority of such effusions are due to tubal pregnancy and the formation of a tubal mole. Mr. Bland Sutton thinks that the term hæmatosalpinx ought to be restricted to the small group of exceptional cases in which the effusion results from some other cause than tubal pregnancy. But, as I have shown in a paper on the subject published in the *St. Thomas's Hospital Reports*, there is a considerable number of cases where the Fallopian tube is found distended with blood-clot, forming a sausage-shaped tumour, and where the evidence of its having originated at a tubal pregnancy is inconclusive. The clinical evidence may be strong, but the most careful search may fail to detect an embryo or chorionic villi or other indisputable product of conception. This being the case, it seems convenient for the present to retain the general term hæmatosalpinx for all effusions of blood within the Fallopian tube, and to qualify the term, wherever the evidence is sufficient to warrant this being done, by a few words indicating the source of the effusion in the particular case. In a certain number of cases the evidence is insufficient for definite classification, and in such cases the term hæmatosalpinx seems the most appropriate designation. If Mr. Bland Sutton's suggestion were adopted, the use of that term would imply that the effusion was definitely known *not* to be the result of a tubal pregnancy. It is because there are undetermined cases that I advocate the retention of the term as applicable to all these effusions.

The formation of a tubal mole precedes most cases of rupture—that is to say, the rupture is more frequently the result of the sudden increase in the size of the contents of the tube due to the extravasation of blood than of mere distension of the tube from the growing ovum. We have already seen that hæmorrhage from the unclosed fimbriated end of a gravid tube is also preceded by the formation of a tubal mole. Hence the tube will be found occupied by clotted blood in almost all cases of intra-peritoneal hæmorrhage associated with tubal pregnancy, whether the blood is encapsulated so as to form a hæmatocele or is freely diffused in the general peritoneal cavity, and whether the hæmorrhage be the result of rupture or occur from the open end of the unruptured tube. It follows that there must be a stage, before rupture or before any hæmorrhage occurs from the open mouth of the tube, when the effusion is entirely intra-tubal. In other words, there are cases of tubal mole or hæmatosalpinx without intra-peritoneal hæmorrhage. I have myself operated in six such cases. In two of them the ovum was found and in four we failed to discover it. But the clinical history left little doubt that all these cases were instances of hæmatosalpinx due to tubal pregnancy. Had they been left to their fate intra-peritoneal hæmorrhage would have been inevitable, either from rupture of the over-distended tube or from escape of the imprisoned blood from the mouth of the tube. In most of the cases rupture was imminent, as shown by the condition of the tube wall. The size of the intra-tubal clot varies greatly. Sometimes it is not larger than a walnut, but it is much more frequently found large enough to distend the whole of the outer part of the tube, so as to form a firm, elongated tumour from one inch to three or four inches in diameter. For when an ovum has once become apoplectic fresh hæmorrhages are apt to occur, and either the clot becomes more bulky or the blood finds its way out from the mouth of the tube. Hence in most cases of pelvic hæmatocele there is associated with the hæmatocele a hæmatosalpinx. When the hæmatocele is, as I have shown it to be in the majority of cases, due to escape of blood from the open mouth of the unruptured tube, the clot is seen protruding from the dilated mouth of the tube, and to be, in fact, continuous with the contents of the hæmatocele.

Up to the end of January of the present year (1897) I had operated by abdominal section in twenty cases of pelvic hæmatocele. This does not, of course, represent all the cases of pelvic hæmatocele that have come under my observation. I am not prepared with a statement of the precise number of cases that I have had under treatment in hospital or seen in consultation, but the total number would, I feel sure, be a fairly large one. In the earlier years of my practice no one dreamed of interfering with a case of pelvic hæmatocele unless there was evidence of suppuration, and even more recently the number of cases in which I have abstained from operating has probably been at least equal to the number in which I have operated. But for my present purpose cases not operated upon were of no value. For exact pathological inquiry it is necessary to see and handle the parts; the evidence afforded by mere clinical examination, however carefully conducted, is insufficient. Further, I have only taken account of ordinary typical cases in which the hæmatocele was the most conspicuous lesion. Cases, for example, where a small effusion of blood was found in the pelvis during operations performed for other conditions, and where the extravasation was a mere incidental complication of the disease for which the operation was undertaken, have been excluded from the list. Taking, then, this series of twenty cases in which the source of the hæmorrhage was verified by operation I obtained the following very remarkable result: Every one of the twenty cases was associated with tubal gestation; but so far from finding the majority of the cases due to rupture I found that rupture had occurred in only one case out of the whole number. In eighteen of the twenty cases the hæmorrhage had taken place from the open mouth of the unruptured tube. In the remaining case a very curious condition of things existed. There was tubal pregnancy, but the immediate source of the hæmorrhage was not the pregnant tube. There was a broad ligament cyst on the opposite side of the pelvis. Into this cyst a profuse intracystic hæmorrhage had occurred, and as a consequence the cyst had undergone rupture, thus giving rise to the hæmatocele. The case was interesting as pointing to the occasional occurrence of accidental sources of hæmorrhage. The fact of the coexistence of a tubal pregnancy on the opposite side may have been a mere coincidence. On the other hand, it may be that the general vascular activity of the pelvis, associated with the pregnant condition, was a factor in

Hosted by Google

determining the hæmorrhage. This, however, is a matter rather of scientific curiosity than of practical interest. The point of real importance is that, so far as the evidence afforded by my own individual experience extends, the part played by rupture in the causation of pelvic hæmatocele is a very small one, much the more usual source being hæmorrhage from the mouth of the unruptured tube. In a note at the foot of the table I have mentioned two

TABLE I.—*Pelvic Hæmatocele; Source Verified by Operation.*

	Cases.
Free end of gravid Fallopian tube	18
Rupture of early tubal gestation	1
Rupture of hæmorrhagic cyst of broad ligament in a case of early tubal gestation	1
	20

Note.—Two cases of late operation (seven months and four months) should probably be added to Class I., but as the evidence was not absolutely conclusive they have been omitted.

cases in which operation was performed at comparatively long intervals after the occurrence of the hæmatocele. The blood had been almost entirely absorbed, and no pathological evidence of gestation was obtained—that is, no embryo or other portion of an ovum. But the clinical evidence was in favour of both being cases of tubal gestation, and as the Fallopian tubes were found in each case empty and unruptured, the probabilities are great that they were instances of complete tubal abortion at a very early stage of pregnancy.

Having obtained this somewhat surprising result from a consideration of all my available cases of pelvic hæmatocele, it seemed to me that it would be worth while to carry the investigation a little further. The result is given in the three following tables. In Table II. I have shown the condition found in each of the thirty-four cases of early tubal gestation operated upon in my own practice. With the cases

in the first series—the cases in which neither rupture nor (extra-tubal) hæmorrhage had occurred—I have at present no further concern. But the remaining two series of cases it is important to consider separately. Taking first the 19 cases of tubal mole, with hæmorrhage from the free end of the tube, it will be seen (Table III.) that a pelvic hæmatocele resulted in 17, whilst in the remaining two the blood was effused into the general peritoneal cavity.

TABLE III.—*Cases of Tubal Mole with Hæmorrhage from the Free End of the Tube.*

Pelvic hæmatocele resulted in	17
Free intra-peritoneal effusion	2
	19

In Table IV. the cases of rupture are subjected to a similar analysis, with the result that seven out of the nine are seen to have been accompanied with a free effusion of blood in the peritoneal cavity; in one case a pelvic hæmatocele was formed, and in the remaining case rupture had occurred extra-peritoneally, forming a hæmatoma of the broad ligament.

The one case of rupture that ended in the formation of hæmatocele is worthy of being given in brief detail. It was that of a married woman, aged thirty-seven years, who was admitted into St. Thomas's Hospital looking very weak and ill and presenting the ordinary physical signs of pelvic hæmatocele of considerable size. She had been confined with her fourth and last child five years previously. Her last menstrual period had ceased on Nov. 24th, 1891. From that time she had suffered more or less continuous pain. On Jan. 20th, 1892, she had been suddenly seized, whilst sitting quietly in the house, with a very violent pain in the right iliac region, which compelled her to go to bed. Two hours later she had a somewhat profuse hæmorrhage per vaginam. There had been two subsequent attacks of hæmorrhage, slighter in character, during the following month, and she had been in constant though less severe pain. She was admitted to the hospital on Feb. 23rd, 1892. The case was diagnosed as pelvic hæmatocele originating in a tubal gestation, and it was decided to watch it. On May 8th painful uterine contractions came on, and a decidual cast of the uterus, of considerable thickness and measuring two and a half inches by two inches, was expelled per vaginam. This, of course, placed the diagnosis beyond doubt. I still continued, however, to watch the case, being prepared to interfere at any moment if the necessity arose. When the patient had been in hospital a month it was found that the swelling had increased in size rather than diminished. I therefore determined to open the abdomen. This was accordingly done on March 21st, four months from the alleged date of the last menstruation, and two months from the date of the first attack of violent pain and hæmorrhage. A mass of dark, firm clot, eleven and a half ounces in weight, was found filling the pelvis, and in the midst of this mass was found a fœtus four inches in length, with cord, placenta, and membranes. The hæmatocele was roofed in by adherent omentum and intestine. After the pelvis had been cleared the dilated and ruptured right Fallopian tube was brought into view and removed. The rent in the tube was a large one and was situated on its posterior aspect. The patient, as almost all these patients do, made an uninterrupted recovery. The history in this case had misled me. The size of the fœtus made it evident that either the patient was mistaken as to her dates and was really eleven or twelve weeks—instead of only eight weeks—pregnant when the first symptoms of internal hæmorrhage occurred, or, what seems very unlikely, the fœtus had continued to live and grow for three or four weeks after the occurrence of the hæmorrhage. Had I known that the pregnancy had advanced so far I should have been sure there was rupture, and should not have waited in the vain hope of a spontaneous cure. The preparation is now in the museum of St. Thomas's Hospital.

I am quite aware that the number of cases on which this investigation is based is too small to furnish material for dogmatic statement. No one is more keenly aware than I am of the fallacies that are inseparable from hasty generalisations on insufficient data. I merely offer these figures as my personal contribution to the study of pelvic hæmatocele. Other observers both in this and in other countries are arriving at similar conclusions. In a recent discussion on pelvic hæmatocele in the Surgical Society of Paris more than one speaker expressed the opinion that insufficient attention had hitherto been given to the important part played by tubal abortion in the etiology of hæmatocele. Martin and Zedel in Germany, and Bland Sutton and John W. Taylor of Birmingham in our own country, have expressed similar views and published cases in support of them. It would in one sense have made this address more complete if I had included in it a *résumé* of recent literature on the subject and added the experience of others to that of my own. But I am disposed to think that not the least useful contributions to the advance of medical knowledge are sometimes to be found amongst those which are based entirely on the writer's own personal experience. A writer knows his own cases best; he knows best how to classify them; he knows which are available for comparison and which are not; and, what is of equal importance, he knows which cases ought to be excluded on the ground of the record being imperfect.

But enough of apology. My figures are before you to be taken for what they are worth. Most practitioners have met with cases in which the signs and symptoms have appeared fully to justify the diagnosis of pelvic hæmatocele, and in which under treatment by rest alone the swelling has entirely disappeared and the patient has recovered. Some have seen several such cases in the course of their experience. Men who are in the habit of reflecting on their cases must have been finding it difficult to reconcile these recoveries with the current teaching. If pelvic hæmatocele is almost invariably due to ruptured tubal pregnancy, how is it that so many cases took a favourable course without operative interference, and, indeed, without active intervention of any kind? The facts I have been permitted to place before you this evening smooth away this difficulty. It is, in my opinion, because pelvic hæmatocele is usually associated, not with rupture, but with hæmorrhage from the open mouth of the tube in a very early stage of tubal gestation that so many cases

Hosted by Google

recover without operation. The embryo is often of insignificant size and is easily absorbed. Along with the diminutive products of conception the effused blood also undergoes absorption. Have we, then, any guide as to when it is safe and when it is not safe to withhold operative influence? It can, I think, only be safe to do this when the clinical history points unmistakeably to the hæmorrhage having occurred within the early weeks of pregnancy. "At a later stage," as I have said elsewhere, "the embryo and other products of conception are too large, and the risk of further hæmorrhage is too considerable for non-operative treatment to be justifiable." Again, whenever the severity of the initial symptoms is sufficient to lead to a suspicion that the case is one of rupture I am of opinion that there should be no hesitation in advising operation. Even where this is not the case, and where the history and symptoms point to a different conclusion, the dimensions of the swelling should be carefully examined from day to day, and when the swelling is found to be increasing, or when, from the repeated occurrence of attacks of pain and faintness, there is reason to believe that hæmorrhage is still going on, then, too, I consider the indications for operation are imperative. I need scarcely add that where the hæmorrhage from a tubal gestation, whether due to rupture or not, is diffused in the peritoneal cavity, the necessity for immediate operation, if the condition of the patient permits it, is indisputable.

A word remains to be said of the rarer causes of pelvic hæmatocele. Whilst preparing this address I received from a Canadian professor of gynæcology, Dr. Wm. Gardner, of the McGill University, a paper containing a clinical record of two cases exemplifying the association of cancer and tuberculosis of the genital organs of women with pelvic hæmatocele. It was a curious coincidence, for they are the only cases of the kind I remember to have seen described. They were unique in Dr. Gardner's own experience, and must be of extreme rarity. A case of my own, included in the tables, shows that the rupture of a cyst into which profuse hæmorrhage has occurred may be occasionally the source of a hæmatocele.

I could also relate cases in which, during the operation for the removal of inflamed uterine appendages, I have unexpectedly opened up intra-peritoneal collections of altered blood, due no doubt to hæmorrhages occurring as accidental complications of the inflammatory process. These and other cases I could cite, from my own records and from those of others, show that there remain exceptional cases unassociated with ectopic gestation. At the same time it is abundantly clear that many of the causes of pelvic hæmatocele enumerated by the older writers are purely hypothetical and that most of the cases attributed to menstrual disturbances, bursting of apoplectic ovaries, rupture of veins, and so on, when read in the light of our present knowledge, are easily recognised as having been misunderstood cases of early tubal gestation.

A MEETING of Fellows of the Royal College of Surgeons of England was held at the Medical Institute, Birmingham, on Wednesday last in support of the candidature of Mr. Bennett May for a seat on the Council of the College. The following resolution was proposed and carried unanimously:—"That this meeting of Fellows of the Royal College of Surgeons desires to express its approval of the candidature of Mr. Bennett May for the seat on the Council vacant by the death of Mr. Oliver Pemberton, and pledges itself to his support."

FREEMASONRY: THE RAHERE LODGE No. 2546.—The Installation meeting of this lodge was held in the Great Hall at St. Bartholomew's Hospital on the 15th inst., W. Bro. Alfred Cooper, P.G.D., the W.M., in the chair. Messrs. Matthews, Miles, and Shewell were initiated into Freemasonry, and Messrs. Gell and Auden were proposed as members of the Lodge, whilst Bro. C. O'B. Harding was proposed as a joining member. Bro. Walsham was then installed by Bro. Trollope as the W.M. for the ensuing year. He appointed Bro. Burns and Bro. Reece as his principal officers and invested Bro. Gripper as treasurer of the lodge. The balance sheet was presented and adopted. It showed that the lodge had a substantial balance, though it had contributed freely to the various masonic charities. A past-master's jewel was presented to W. Bro. Alfred Cooper. The lodge was then closed, and the brethren with their guests betook themselves to Frascati's Restaurant, where they dined together to the number of seventy-three.

ABSTRACT OF

Lectures

ON

DISEASES OF THE GALL-BLADDER AND BILE-DUCTS.

Delivered at the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1897,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE III.[1]

Delivered on March 12th.

Gall-stones or Cholelithiasis.—The importance of this subject may be gathered from the facts, that post-mortem records on persons of all ages and both sexes, prove gall-stones to be present in from 5 to 10 per cent. of all Europeans, in Strasburg the record being 12 per cent. (Schroeder), in Kiel 5 per cent., and in Manchester 4·4 per cent. (Brockbank). Time will not permit me to enter on the pathology of the subject, although it is of such great interest, nor can I discuss the causes, composition, sizes, numbers, or varieties of gall-stones or enter into the ordinary symptoms, complications, diagnosis, and medical treatment, all of which subjects I have recently written on in my article in Professor Clifford Allbutt's System of Medicine. I must therefore at once pass on to the consideration of the surgical treatment of cholelithiasis, a subject of great importance, which will, I think, well repay careful study. Permit me, first, to draw your attention to the list of cases on which I have operated and which will serve as a basis for my further remarks. An analysis of the table shows that out of 170 operations of all classes, including malignant cases, 10 patients died. Of the 93 patients without jaundice all recovered, all the deaths occurring among the 77 jaundiced cases. Of the 10 patients who died, only 4 were the subjects of gall-stones, and they had deep jaundice or infective cholangitis, or both, at the time of operation; the remaining 6 were for the most part the subjects of malignant or other fatal diseases. Out of 115 cholecystotomies there were 5 deaths, 3 being the subjects of cancer and 2 of suppurative cholangitis with jaundice; in other words, the mortality of cholecystotomy for gall-stones is only a little over 1 per cent. There were 7 cholecystectomies with 1 death, which is equivalent to a mortality of 14·28 per cent. That death was due to want of efficient drainage. Of the 26 cholelithotrities all recovered. Choledochotomy furnishes 6 cases in the list, out of which 1 patient died, as the result of an accidental laceration of the intestine in separating adhesions not noticed at the time of operation. The mortality equals 16·6 per cent. Of the 11 cholecystenterostomies one died; and as that patient was the subject of extensive malignant disease, the percentage mortality of the operation for gall-stones is therefore *nil*. Of the abdominal sections, 32 in number, 2 patients died from shock and hæmorrhage. These were among the 19 operated on for tumours or other serious organic disease; but out of the 11 operated on for separation of adhesions, 3 for intestinal obstruction and 1 for peritonitis, all recovered.

Surgical treatment—After medical treatment has been fairly and fully tried, and failed, I think all are now agreed that surgical measures should be resorted to. While cholecystotomy is generally recognised as the operation to be aimed at in the treatment of affections of the gall-bladder or bile-ducts, especially in cholelithiasis, it is often impossible to say what operation will have to be done until the abdomen is opened. The indications for operating would seem to me to be as follows:—1. In frequently recurring biliary colic without jaundice, with or without enlargement of the gall-bladder. 2. In enlargement of the gall-bladder without jaundice, even if unaccompanied by great pain. 3. In persistent jaundice ushered in by pain, and where recurring pains, with or without ague-like

[1] Lectures I. and II. were published in THE LANCET of May 29th and June 5th respectively

Hosted by Google

paroxysms, render it probable that the cause is gall-stones in the common duct. 4. In empyema of the gall-bladder. 5. In peritonitis, starting in the right hypochondrium. 6. In abscess around the gall-bladder or bile-ducts, whether in the liver, or under, or over it. 7. In some cases where, although gall-stones may have passed, adhesions remain and prove a source of pain and illness. 8. In fistula, mucous, muco-purulent, or biliary. 9. In certain cases of chronic jaundice, with distended gall-bladder dependent on some obstruction in the common duct, although the suspicion of malignancy be entertained. In such cases the increased risk must be borne in mind, as malignant disease may be the cause of the obstruction, and operation in such cases is attended with greater danger than ordinary. 10. In phlegmonous cholecystitis and in gangrene, if the case be seen and recognised at a sufficiently early stage of the disease. 11. In gunshot injury or in stab wounds over the region of the gall-bladder. 12. In suspected rupture of the gall-bladder without external wound. 13. In some cases of chronic catarrh of the gall-bladder or bile-ducts. 14. In suppurative cholangitis. Of the operative measures undertaken for diagnosis, sounding and aspiration of the gall-bladder must be referred to. The so-called "sounding for gall-stones," either by means of a probe passed through a cannula or by the fine needle of an aspirator, is both uncertain and dangerous, and may more safely be replaced by a small exploratory incision, which can be extended for treatment if required. Aspiration of a distended gall-bladder through the unopened abdomen, though apparently a simple procedure, is not unattended with danger, death having followed in more than one instance. Murphy says it is fatal in 25 per cent. It is only in very exceptional cases that it can do any good. Here, again, I infinitely prefer to make a small exploratory incision, then to empty the gall-bladder by the aspirator, and afterwards to explore the bile passages with the fingers. If, however, aspiration without exploration be decided on, a small needle should be used and the cyst emptied as far as possible, in order that intra-cystic tension may not lead to extravasation through the needle puncture. Since in the majority of cases an operation for gall-stones is, in the first place, simply exploratory, the actual operation on the gall-bladder or bile-ducts being only determined by the conditions found when the abdomen is opened, it may be well for us first to consider a simple abdominal section in the gall-bladder region.

Position of the patient.—It has been proposed to suspend the upper part of the trunk when the patient is on the operating table by straps placed under the armpits, in order to allow the intestines to fall away from the liver, and thus to afford a better view of the parts to be operated on, just as the Trendelenberg position does in the case of the pelvic organs; but as this is inconvenient, and, as a rule, impracticable, it is worth considering whether we can in any way modify it. I think it will be found that a narrow, firm sand bag covered with flannel placed at the liver level on the operating table under the back, which is thus arched over it, will do all that is required, as it brings the common duct from two to three inches nearer the surface, opens out the costal angle, and tends to make the intestines slip down from the liver. I have never seen or heard of this method having been made use of by others, but as I have employed it on many occasions I can speak well of its utility.

Incision.—A vertical incision in the right semilunar line is the one most frequently resorted to, and is the one I prefer. If there be a perceptible tumour, it is well to make the incision over the most prominent part; if there be no tumour, but an enlarged liver, the upper end of the incision will have to commence at the hepatic margin. If, however, as is so often the case, there be neither tumour nor enlargement of the liver, the incision will be from the ninth costal cartilage vertically downward for three inches. As a rule the aponeurosis in the semilunar line is divided; but if the rectus be wide, its fibres may be separated, and the anterior and posterior layers of the rectus sheath will then be separately cut. If more room be required it can be obtained either by extending the vertical incision or adding a transverse one, either internal or external to the vertical line, in whichever direction it may seem advisable. It is advisable to avoid as much as possible dividing muscular fibres, as they retract, and can only with difficulty be approximated in suturing the wound. The transversalis fascia and peritoneum are best divided together, without separating them, as together they form a strong membrane, whereas singly they are too weak to hold stitches if there be tension. Kocher employs an oblique incision parallel to the right costal margin, which of necessity divides muscle, but which exposes the parts freely, as the wound at once gapes widely, although for cholecystotomy the transverse incision is quite unnecessary and to my mind usually inadvisable. Where it is necessary to expose or manipulate the common duct it presents the advantages of better exposure and more efficient drainage. The lumbar incision, which has been suggested in order to reach the common duct without opening the peritoneum, is quite impracticable.

Arrest of hæmorrhage.—As a rule pressure forceps and an occasional ligature effect all that is desirable or necessary, but in cases of long-standing jaundice, especially if accompanied by malignant disease, additional precautions are advisable on account of the tendency to hæmorrhage. In order to avert this danger in deeply jaundiced patients I have found the administration of chloride of calcium in 30-grain doses every four hours for a few days before the operation useful in making the blood more plastic and in lessening the tendency to bleeding, both at the time of operation and subsequently. For this therapeutic measure I am indebted to Dr. A. E. Wright, whose researches on the "Coagulability of the Blood"[2] are well worthy of study. After operation, the drug may be continued either by the mouth or by nutrient enema for some time with advantage. In order to remove the danger of ventral hernia I suture the abdominal wall, layer by layer; but if the operations have been very prolonged, and the patient be suffering from shock, it may be advisable to suture the parietes *en masse*. Where it is considered wise to employ gauze packing it is well to apply the sutures and to leave them long, so as to be able to draw the edges of the wound together after the tampon has been removed, without putting the patient to the inconvenience of inserting stitches later. The preliminary preparation and the after treatment of these cases differ in no respect from that of abdominal section in general. Cholecystotomy or cholecystostomy usually follows on exploration, as it is unquestionably the operation *par excellence* in the treatment of gall-stones. The indications for the operation are:—1. In all cases where the gall-bladder is sufficiently large to permit of drainage, after gall-stones have been removed from the gall-bladder or ducts. 2. In cases where there are gall-stones in the ducts, but the patient is too ill to bear a prolonged operation, the gall-stones being deliberately left for treatment by some solvent solution. 3. In empyema of the gall-bladder where that viscus is not too much disorganised to be permitted to remain. 4. In certain cases of chronic catarrh of the gall-bladder or bile-ducts. 5. In suppurative cholangitis. 6. In obstruction of the ducts due to hydatid disease. 7. In dropsy of the gall-bladder. 8. In idiopathic rupture, or laceration, or gun-shot injury of the gall-bladder or ducts. 9. In cases of choledochotomy in order to avoid tension in the sutured duct. 10. In certain cases of obstructive jaundice dependent on malignant tumour, which is occluding the ducts; but in these cases the increased danger must be borne in mind. 11. In some case of phlegmonous cholecystitis or gangrene, where the patient is too ill to bear cholecystectomy.

Technique.—If the gall-bladder be found distended it is aspirated and then opened, the parts being isolated by thin, flat sponges. If, as is so often the case, the gall-bladder be small and atrophied, it will probably be surrounded by adhesions which require careful separation, which can for the most part be better done by touch than sight. If the operation has been undertaken for gall-stones they are removed by means of forceps passed through the opening in the gall-bladder, or, better still, by the scoop which I now show. If they be small they are removed whole; if large they may be directly needled or crushed and removed in fragments. After the gall-bladder has been cleared the fingers of the right hand are passed along the outside of the ducts, when if there be any other concretions they can as a rule be felt, and if possible they should be manipulated backward into the gall-bladder, from which they can be removed. If this be impracticable, without undue force, cholelithotripsy or choledochotomy may be necessary, which operations I shall consider later. Supposing the bile passages to have been cleared, or for some reason further manipulations are considered advisable, a non-perforated rubber drainage tube is inserted into the gall-bladder, and the edges of the incision in it are brought up

[2] Brit. Med. Jour., Dec. 19th, 1891.

Hosted by Google

and sutured by fine chromic catgut to the aponeurotic layer of the abdominal wall, not to the skin, thus avoiding the danger of fistula, as between the opening in the gall-bladder and the skin is a considerable thickness of tissue, which soon becomes covered with granulations, and their contraction in healing secures closure. Since adopting this method I have never had a fistula follow cholecystotomy if the ducts have been cleared. Where there is time, I prefer to suture the peritoneum of the gall-bladder to the parietal peritoneum, and the mucous margin to the aponeurosis, thus more completely shutting out the peritoneal cavity. The remainder of the parietal incision is closed as described under simple exploratory incision. In ordinary simple cases, the drainage tube is shortened on the second and third day, and removed on the fourth or fifth; but if there have been much cholecystitis, or cholangitis it is better to drain for a week or even longer. Dr. Terrier, in operating for suppurative cholangitis, suggests that the discharge should be bacteriologically tested from time to time, and that the tube should not be removed until the bile is sterile or nearly so, for at first it is loaded with organisms, and if all goes well these diminish and finally disappear. The tube may be either cut off close to the surface or may be brought through the dressings into a receptacle placed by the side of the patient; the latter method saves frequent dressings, which are otherwise necessary when the discharge is free. This description applies to the ordinary operation on a gall-bladder of ordinary size, or to one distended; but in the case of a contracted gall-bladder situated deeply the operation may be both prolonged and difficult. Where I have been unable to bring up the gall-bladder I have at times succeeded in tucking down the parietal peritoneum to the edges of the gall-bladder opening, and so effecting suture of the contiguous margins; but in several cases where I could not effect this I have with complete success utilised the right border of the omentum, by suturing it to the margin of the gall-bladder opening and to the parietal peritoneum, thus forming a tube of peritoneum around the drainage-tube and shutting out the general peritoneal cavity. This method has also since been efficiently employed by Mr. Arthur Barker. Where occlusion in this way cannot be effected, the insertion of a drainage-tube into the gall-bladder without suture of the margins to the parietes seems to be efficient, for it is, on account of intra-abdominal tension, easier for the bile to pass away directly through the tube than to enter the abdomen, and it is probable that within from 24 to 48 hours plastic peritonitis shuts out the drainage-track from the general peritoneal cavity. The method of packing around the tube with iodoform gauze in such cases is one in which I have great faith, as I have found it to be a safe means of occluding the peritoneal cavity. Mr. Knowsley Thornton suggested supra-pubic drainage in cases where occlusion of the bile channels is doubtful, but if I require to drain the abdominal cavity in such cases I prefer to do it either by means of a tube passed into the right kidney pouch and brought out at the lower end of the original incision, or through a stab puncture in the right loin. Dr. Murphy has invented a "button tube" (which I now pass round) for use in cases where the gall-bladder is contracted and cannot be brought to the surface, but in practice I have found that the contracted gall-bladder is as a rule too small to permit of its employment, and though I have taken it with me regularly to a number of operations I have never yet met with a case where I thought it desirable to employ it. In certain cases where the gall-bladder is contracted, after opening and clearing it and the ducts, the incision may be immediately closed by suture, the line of incision being isolated by a gauze drain; or in other cases cholecystectomy may be performed and the cystic duct ligatured, the gauze drain being again employed; or, as suggested by Mr. Morison, the incision in the gall-bladder may be deliberately left patent and the bile allowed to run into the right kidney pouch, from which it is removed by a drainage tube in the loin. The operation of cholecystotomy has been modified in several ways; for instance, the opening has been closed and then fixed to the abdominal incision, which has been closed over it; this operation is known as cholecystendysis (Courvoisier). It can only be of use where the ducts are known to be thoroughly cleared, where there is no fear of subsequent stricture, and where there is no catarrh or inflammation of the bladder or bile passages. The so-called "ideal" operation suggested by Langenbach,[3] in which the opening in the gall-bladder is sutured and the viscus returned without fixing it to the surface, has been thought by Lange, Meredith, Kuster, Keen, and others to be attended with greater risk than the operation of cholecystostomy. If it be thought advisable to adopt this method, it is necessary to prove that the ducts are clear, and this may be accomplished by distending the gall-bladder with warm sterilised water and then forcing it through the ducts, or by catheterism of the ducts, as advocated by Terrier and Dalby.[4] I have employed both methods, but prefer the former, both on account of its safety and efficiency. Recently reported cases of "ideal" cholecystostomy would seem to prove that the dangers at first attending the operation may be overcome by a proper selection of cases and by carefully suturing the mucous, muscular and serous margins separately; but I think the serious objection to it is that the benefits of drainage are not obtained, as in the operation of cholecystostomy. A real use for this modification is found in cases where it has been necessary to open a contracted gall-bladder, but where, on account of the depth, it is found impracticable to bring it to the surface; as also when, from the contraction of its cavity, it is found impossible to insert a drainage tube. Under such circumstances sutures can readily be applied by means of a rectangular cleft palate needle or by Lane's needle-holder. The line of suture is made secure against dangerous leakage by the gauze drain, the lower end of which is packed moderately firmly over the gall-bladder. Another modification, suggested by Bloch, is that in two stages. The operation consists in incising the parietes until the peritoneum is reached, the cavity of which, however, is not opened; the wound is then packed with gauze and left for several days, when adhesions will have formed between the gall-bladder and the parietal peritoneum. The gall-bladder can then be safely opened. Or if the peritoneum be opened, the gall-bladder is fixed, but not opened until adhesions have formed. As the method is only available for the simplest cases—viz., where the gall-bladder is distended—as it does away with all chance of exploring the ducts by the hand within the abdomen, and as it is frequently followed by fistula, I would only mention it to condemn it as clumsy and uncertain and no safer than the ordinary operation of cholecystotomy. In this opinion I would make one exception, I think the operation "à deux temps" presents considerable advantages when cholecystotomy is being undertaken in the presence of chronic jaundice associated with distended gall-bladder, as in such cases there is usually malignant disease either of the head of the pancreas or of the bile-ducts, and when the peritoneum is exposed, but not opened, pressure can be applied to arrest the oozing of blood, which cannot always be stopped by ligatures or forceps. Bloch, however, in his original papers and in his latest in the *Revue de Chirurgie* for 1895, does not recommend the operation for this reason, but on account of the fear of septic contamination of the peritoneum, which ample experience proves to be groundless. The statistics of cholecystotomy vary very considerably in different hands. As in ovariotomy, experience leads to greater success, and those who have done a considerable number of operations will as a rule show the best results. Out of 115 cholecystotomies which I have performed there were five deaths, three being the subjects of cancer and two of infective cholangitis with jaundice. In other words, the mortality from cholecystotomy for gall-stones is only a little over 1 per cent., or, including malignant cases, 4·34 per cent. Murphy, at the Roman Congress, collected 201 cases of cholecystostomy, the mortality being 19 per cent. Mr. Page (Newcastle) has been so kind as to furnish me with the result of operation at the Newcastle Infirmary, where out of twenty-four operations six died. Mr. Charters Symonds has performed eight operations, with recovery in all. With regard to recurrence, if the ducts be cleared and the gall-bladder drained recurrence is rare. Kehr says of his cases that there has been no recurrence.

Fistula following cholecystotomy.—An eminent operator recently told me that he thought fistula frequently followed on cholecystotomy. I suppose he was arguing from his own experience, which, however, is quite at variance with mine, since I have adopted the modification of suturing the edge of the gall-bladder incision to the aponeurosis and not to the skin, for it distinctly proves that fistula will only follow under such circumstances if the

[3] Centralblatt für Chirurgie, 1887.

[4] Revue de Chirurgie.

Hosted by Google

ducts have not been cleared, and then it is better that there should be such a safety valve, which can be remedied by a further operation. In my first ten cases I had five fistulæ; these were all operated on by stitching the gall-bladder to the skin. In my later 160 cases there were only seven fistulæ, all of which were cured by further clearing the ducts or short-circuiting the obstruction. As one would expect, cholecystotomy "à deux temps" is often followed by fistulæ. Martig gives 20 per cent. and Courvoisier 34 per cent., which, of course, are due to imperfect clearing of the ducts. After cholecystotomy has been performed and the gall-bladder cleared of its contents it may be found impracticable to remove other gall-stones impacted in the cystic or common ducts, either by means of forceps or scoop introduced through the gall-bladder incision, or by digital manipulation from without. Under such circumstances the gall-stones may be crushed or removed by "choledochotomy," or under certain circumstances "cholecystenterostomy" may be performed. As crushing is the least severe procedure, and as I have had considerable and favourable experience of it, I will describe that operation first.

Calculi in the common bile-duct.—Before proceeding to a description of cholelithotrity or choledochotomy it may be advisable to refer to the special condition of cholelithiasis, where the gall-stones are in the common duct, which, according to Courvoisier, occurs in about 4 per cent. of all cases. A reference to the cases that have come under my care shows this to be an under-estimate, as I find that out of 170 cases on which I have operated there were gall-stones in the common bile-duct on 28 occasions, which equals 20 per cent. My experience shows a much larger proportion of multiple calculi in the common duct. In my paper read before the Clinical Society of London in 1888, and again on page 82 of my work on Gall-stones published in 1892, I drew attention to contraction of the gall-bladder as an important diagnostic point, and this has been borne out by other observers independently. I then remarked that jaundice with distended gall-bladder was presumptive evidence in favour of malignant disease, but that jaundice without distended gall-bladder favoured the diagnosis of cholelithiasis. Of thirty-five operations for obstruction in the common duct, Courvoisier found that eighteen were due to causes unconnected with gall-stones, such as cancer, stricture, or tumour; of these, the gall-bladder was dilated in sixteen, whereas only seventeen were dependent on gall-stones and of these seventeen the gall-bladder was atrophied in thirteen. I think the explanation is to be found in a combination of causes: (1) All cases of cholelithiasis are accompanied by inflammation of the walls of the biliary passages, as shown by the almost universal presence of adhesions around the gall-bladder; (2) gall-stones in the common duct seldom cause complete obstruction, either because they are floating in the duct or because they only partially fill it, there is, therefore, no sufficient backward pressure to cause dilatation of the gall-bladder; (3) the muscular coat of the gall-bladder, though feeble, is sufficient to enable it to contract, which it doubtless does in efforts of expulsion when there is any obstruction in the common duct; and (4) the contraction, from being at first intermittent, becomes in the long run constant, and the accompanying inflammation fixing the contracted gall-bladder, it atrophies. The special symptoms pointing to stone in the common duct are absence of enlargement of the gall-bladder, with frequent mild attacks of pain, followed by an intensification of the jaundice, which in many cases never quite disappears. The seizures are often associated with intermittent feverish attacks and loss of weight. The pain is in the epigastric rather than in the right hypochondriac region, and passes through to the right dorsal or lumbar, rather than to the right infra-scapular, region. Where jaundice is continuous and intense without much variation, especially if the gall-bladder be enlarged, there is usually malignant disease or some other cause than gall-stones. All the other symptoms characteristic of gall-stones may have been present for some time previously or may coexist with those above mentioned.

Methods of Treatment.—The treatment of calculous obstruction in the common duct is of the utmost interest, both on account of the difficulties to be overcome and of the great importance to the patient, who in the greater number of cases is otherwise condemned to a lingering and painful illness, often ending in death. 1. In a few cases a concretion of moderate size may be manipulated backwards into the cystic duct, and thence extracted by scoop or forceps; but it is seldom practicable on account of the contraction of the gall-bladder and cystic duct. 2. Occasionally a small stone may be pressed into the duodenum, but this is rare, and not infrequently it may be pushed into a dilated diverticulum of Vater, and so be missed, and the whole operation rendered futile. 3. Cholecystostomy, with subsequent treatment by solvent injections, is well worth bearing in mind, on account of its simplicity and safety, together with the certainty of giving immediate relief with a modicum of risk, and putting the patient in better condition for subsequent treatment, should such be necessary. 4. Cholelithotrity, or crushing the stones *in situ*. 5. Needling concretions through the duct walls. 6. Choledochotomy, or incising the duct and removing the calculi. 7. Choledocho-duodenotomy, or reaching the duct through the opened duodenum, for stones impacted in the duodenal end of the duct. 8. Cholecystenterostomy, or short-circuiting the obstruction. 9. Choledochenterostomy, or uniting the duct to the gut in case of largely dilated ducts. 10. Choledochostomy, or attaching the dilated duct to the surface and draining it. It will thus be seen that the surgeon has a great variety of operations to choose from, and he will act the wisest, who, knowing all, is able to choose that peculiarly adapted to the case in hand. The various operative procedures I propose to consider in detail. Cholelithotrity was first suggested and put in practice by Mr. Lawson Tait, and has since been extensively and most successfully employed by him, by myself, and others. The ordinary incision for cholecystotomy may be large enough, but if the patient be stout, or the ducts cannot easily be reached, it may have to be increased so as to allow the hand to pass into the peritoneal cavity, in order that the fingers may locate and grasp the stone *in situ*. If the right hand be used the thumb will enter the foramen of Winslow and the index finger will pass in front of the common duct, or in case of the left hand being used these digits will be reversed, when the whole force of the opposing finger and thumb can be brought to bear on the concretion. I have found by experiment that this force amounts in my own hands to ten kilogrammes without support to the fingers, and thirteen when the fingers are supported. Usually the gall-stone flattens out into a wafer shape, and in altering the position of the digits the edges of the wafer are compressed and the concretion is either converted into pulp or breaks into innumerable fragments, which can be passed on towards the duodenum or subsequently washed through. I have performed this operation twenty-seven times and have had no subsequent trouble on account of damage to the ducts. In some cases of stones in the common duct the concretions have been too hard to crush, and I have had to perform choledochotomy. The disadvantages of cholelithotrity are (1) the fear of seriously damaging the ducts by the manipulation; and (2) the danger of leaving fragments permanently in the passages, which may then grow by further deposit of cholesterine. I have shown by my cases that the first danger need not be feared if the finger and thumb only be used as the compressing force, but I think it might be real if attempts were made to crush hard stones by instrumental means, although I did employ padded forceps to some of my earlier cases. The question of needling impacted concretions by the passage of a needle through the walls of the duct was raised by my colleague, Mr. Teale, in 1895. In my work on Gall-stones published in 1892 (p. 144) I referred to the subject, and Mr. Knowsley Thornton has employed it. It was also fully discussed after a paper I read at one of the societies, and I think it was almost unanimously decided that, although concretions might be broken up by needling, the operation was inadvisable on account of the almost unavoidable damage to the ducts and the fear of infection. It may, however, be borne in mind that some of the very hard stones may be broken up by means of a needle, and that the fragments may be further crushed between the finger and thumb. The second danger—of leaving fragments in the ducts—may be overcome by at the same time performing cholecystotomy and later syringing the ducts with sterilised water until they are clear of débris, or, if any fragments should be unavoidably left, by applying through the fistula some solvent solution. In one case, after cholecystotomy with crushing of calculi in the common duct the fragments did not pass until I injected a few drops of a solution of turpentine in ether into the fistula. Great pain followed, the duct became patent, and the fistula closed, the patient having

Hosted by Google

remained well since. The result in this case was probably rather due to the contractions set up in the duct than to the solvent action of the remedy used, and I cannot, on account of the severe pain set up for some hours, recommend its employment, though in this case the result was good. A more efficient method, which I now employ whenever I have reason to think that any of the fragments remain in the ducts, or wherever I have deliberately left a gall-stone which I could not crush and did not think it wise to remove by choledochotomy, is to syringe a warm 0 5 per cent. solution of sapo animalis or warm olive oil through the fistula night and morning until the passages are quite free. The olive oil and soap solution probably act in a double capacity as solvents and as lubricants. Dr. Brockbank found that a gall-stone placed in a 0·5 per cent. solution of sapo animalis in distilled water, and kept at the body heat in an incubator, lost 34 per cent. of its original weight in three weeks, and that a similar concretion in a 0·1 per cent. solution lost 14 per cent. of its weight in the same time.

Choledochotomy or choledocholithotomy is the name given to the operation of incising the bile-ducts for the extraction of gall-stones in cases where the concretions cannot otherwise be removed. It was probably first suggested by Langenbach in 1884, though Kummell (quoted by Fenger) stated in 1890, that he, several years before, had performed cholecystectomy on a female patient aged forty years, after which he had removed a stone the size of a walnut from the common duct through an incision which he afterwards sutured. The operation was a very prolonged one, and the woman died twenty-four hours afterwards. Courvoisier performed the first successful operation on Jan. 22nd, 1890, and two others, both successful, in February and March of the same year. It has since been performed by Langenbach, Thornton, Fenger, Greig Smith, Page, Terrier, Symonds, myself, and others. The cholecystotomy incision must be extended to four or five inches, and after the separation of adhesions the wound must be held open by a retractor on the right and preferably by an assistant's finger on the left, as the fingers can at the same time retract the pylorus and stomach on the left, and the colon and omentum below without inflicting injury, as retractors are apt to do. The assistant who is using the retractor on the right may with advantage use his left hand to draw upwards the overhanging liver and costal margin. The operator should now, after having separated adhesions, have a good view of the common duct within the free border of the lesser omentum, and on inserting his left index finger into the foramen of Winslow, or on grasping the duct between the index finger and thumb, he can without difficulty bring the duct well within reach, the concretion making a distinct projection. Over the prominent stone a vertical incision as low down and as far forward as possible should be made sufficiently large to allow the concretion to pass. Through this opening a probe can be passed, or even a finger, in order to explore the ducts thoroughly, so as to remove other stones if present. The incision in the duct may now be closed by interrupted sutures in two layers, first the muscular and fibrous coats being approximated, and secondly the serous margins; but if this be impracticable the muscular and serous coats may be sutured together and additional Lembert's sutures may be applied over all. I have found a rectangular cleft palate needle the most convenient instrument to employ in applying these deep sutures, though doubtless a small circular intestinal needle and holder will answer equally well, or the special needles and holder suggested by Mr. Lane may be found more convenient. If a gall-stone be felt in the hepatic duct it may be reached by opening the common duct and passing a scoop or forceps through this opening. Fenger has in this way explored the ducts and removed stones quite in the liver substance, and I have passed a long bent probe in this way quite into the primary division of the bile-ducts. Dr. Elliott recommends the application of the sutures before removing the stone. This is certainly an advantage, though if the ducts have to be explored afterwards the sutures are rather in the way. I think the same advantages may be obtained by introducing the two end stitches before extracting the calculus, as when they are drawn on the edges are approximated and more easily sutured. A large drainage-tube should be left in the abdomen, and it may be wise to pack gently iodoform gauze over the duct and to bring the end out by the side of the drainage-tube, if there be any doubt about the closure of the wound in the duct. The tube may be removed in twenty-four or forty-eight hours if there be only a little discharge, and the gauze should be gradually removed day by day until it is all away. Drainage through a stab wound in the right loin is an efficient means of draining the discharge from a leaking gall-bladder or bile-duct. Mr. Frederick Page, on the other hand,[5] advocates careful suture of the opening in the duct and closing the abdomen without leaving in a drainage-tube. Mr Greig Smith says that drainage is always advisable, and in this view I fully agree, as although in several of my cases there has been little or no discharge from the drainage-tube, in others the bile-stained discharge for a few days has proved that the closure of the opening was not perfect, and it must be borne in mind that although the ducts appear to be clear it is impossible to be absolutely certain, as was proved in one of my cases, where, under the supposition that I had effectually cleared the common duct, I removed a shrivelled and mutilated gall-bladder and ligatured the cystic duct, with the result that septic bile became extravasated into the peritoneal cavity and led to my only death from cholecystectomy. A small gall-stone was found obstructing the orifice of the duct where it was opening into the duodenum. The same difficulty was experienced in one of Fenger's cases and in several of Kehr's.

Choledocho duodenostomy is a term applied to the modification of the operation of choledochotomy, where a gall-stone is impacted in, and removed from, the diverticulum of Vater through an incision in the duodenum. McBurney,[6] Pozzi, and Kocher[7] have performed this operation with success. The operation is difficult and should only be done where the gall-stone cannot be brought into the more accessible part of the common duct.

Statistics of Choledochotomy.—As this is perhaps the most difficult and prolonged of the operations on the bile-ducts, the mortality is necessarily greater than that of simple cholecystotomy. In 1892 Martig had collected 27 cases, and in 1895 Mermann 17 others, giving a total of 44 cases, with a mortality of 18 per cent. Terrier, in 1892, had collected 20 cases, with a mortality of 25 per cent.[8] Hans Kehr,[9] collected from various sources 84 cases of choledochotomy, with 31 deaths (=37·8 per cent.). Even excluding severe cases the mortality was 25 per cent, though in his own practice the death-rate was only 6·6 per cent. He remarks: "The operation involves many difficulties which can only be overcome by one performing a large number of operations, and even then it is not very easy to remove all the concretions." Out of 30 cases, in 5 all the stones were not removed; in 3 the operation was repeated; and in 2 cases the wound reopened and gave exit to the calculi that had been left. Fenger has reported 5 cases, of which 1 died (=20 per cent.). Murphy 5 cases, of which 2 died (=40 per cent.). My own cases are 6 in number, out of which I have lost one, due to the accident of a slight laceration of the colon in separating adhesions (=16·6 per cent.).

Cholecystectomy, or excision of the gall-bladder, may be required in (1) bullet wound or other wound of the gall-bladder where suture is impracticable; (2) in phlegmonous cholecystitis; (3) in gangrene of the gall-bladder; (4) in multiple or in perforating ulcers; (5) in chronic cholecystitis from gall-stones, where the gall-bladder is shrunken and too small to drain safely and where the common duct is free from obstruction; (6) in mucous fistula due to stricture of the cystic duct; (7) in hydrops of the gall-bladder due to stricture of the cystic duct, as also in certain cases where the gall-bladder is very much dilated; (8) in certain cases of empyema where the walls of the gall-bladder are very seriously damaged; and (9) in cancer of the gall-bladder. It is contra-indicated in all cases of non-patency of the common duct, and it should not be resorted to under the idea that it will prevent the formation of gall-stones, as calculi may form in the bile-ducts within the liver or below it. The operation is performed through the usual incision for reaching the gall-bladder. The peritoneum covering the gall-bladder just below the liver is incised parallel to the hepatic margin, and the gall-bladder is freed by means of a finger or a blunt dissector as far back as the cystic duct, the latter part of the dissection being done sub-peritoneally as much as possible. The duct is ligatured and divided, the stump being asepticised either by the cautery or by the application of a 1 in 500 solution of perchloride of mercury. The peritoneum is now sutured over the top of the duct. There is

usually little bleeding, and that is easily arrested by sponge pressure or by one or two ligatures. Unless there be oozing, or unless the wound has been infected by pus or gall-bladder secretion, drainage may perhaps be thought unnecessary; but the adage, "when in doubt drain," is a good one, and it can do no harm to leave an efficient drainage-tube in the right kidney pouch for twenty-four or forty-eight hours after extirpation of the gall-bladder. Packing with iodoform gauze in these cases is better than using a tube, as it serves the double purpose of arresting oozing from the lacerated liver and acting as a drain.

Statistics.—Mortig has collected 87 cases of cholecystectomy with 12 deaths and 3 indirect deaths,[10] thus giving a mortality of 17·24 per cent; Kehr 21 cases with 1 death, equal to 5 per cent.; and Murphy gives the mortality up to 93 as being 17 per cent. I have performed the operation seven times with 1 death, giving a mortality of 14·28 per cent.

Cholecystenterostomy consists in establishing an artificial opening between the gall-bladder and intestine, duodenum, jejunum, or colon, preferably the first, when it may be termed cholecystduodenostomy. Although the conception of the operation occurred independently to Harley, Gaston, and Nussbaum, the first operation was actually performed by Winiwarter of Liege in 1880, and my own case in 1889 was the first of the kind performed in England, and the first anywhere for biliary fistula. In its place it is an extremely useful operation, but as it leaves the cause of the obstruction unremedied it ought not to be resorted to except occasionally, where a more radical operation is impracticable or inadvisable. Dr. Murphy, of Chicago, favours the procedure before other methods.

My conclusions are, that the operation is indicated:—1. In biliary fistulæ, depending on stricture or other permanent occlusion of the common duct. 2. Very occasionally in cancer of the head of the pancreas or malignant tumour of the common duct leading to chronic jaundice and distended gall-bladder; but in such cases the mortality will necessarily be so high that the justifiability of the operation is questionable. 3. Occasionally in impaction of gall-stones in the ducts, where the patient is not in a fit condition to bear the more prolonged operation of separating adhesions, and crushing or removing the concretion by choledochotomy. 4. In certain cases of obstruction of the cystic duct where cholecystectomy is impracticable.

Contra indications.—1. In any obstruction of the bile-ducts which can be cleared away with reasonable probability of success. 2 In malignant disease of the head of the pancreas or common bile-duct leading to distension of the gall-bladder the mortality is so great (eight operations with seven deaths) that it is hardly worth doing. 3 In contracted gall-bladder, where it is impracticable to insert the button. 4. Where there are extensive adhesions which would lead to kinking of bowel. 5. In very large gall-bladder with obstruction of the cystic duct, where cholecystectomy should be done. The operation may be performed: (*a*) by means of simple suture; (*b*) by means of my decalcified bone bobbin; and (*c*) by means of Murphy's button. My first case, in 1889, was performed by suture, my second and third cases by means of the decalcified bone bobbins, and in all my later cases I have used the Murphy button. Although all the cases when the operation was unassociated with cancer recovered, I decidedly prefer to make the union by means of the Murphy button, both on account of its efficiency and the expedition with which it can be used. The operation of cholecystenterostomy is performed through the same incision as is made for cholecystotomy, and after the gall-bladder has been aspirated and the intestine clamped either by an indiarubber tourniquet or by intestinal clamps the junction is effected. If sutures be employed, a semicircle of interrupted silk stitches is inserted to unite the contiguous serous surfaces of the gall-bladder and gut, the viscera are then opened, and the mucous margins of the two openings are united by interrupted catgut stitches, after which the circle of catgut stitches and then the circle of serous sutures is completed. If the bone bobbin be used, two continuous sutures only are employed, a silk stitch to unite the serous surface one-third or one-half of an inch from the visceral openings, and a catgut suture to join the mucous margins of the visceral openings. For convenience, the posterior semi-circle of the serous suture is first applied and the needle laid aside for a moment, but not unthreaded; the openings are then made and the posterior half of the mucous suture is inserted; the bobbin is then introduced and the mucous suture continued around until it meets the other end of the catgut, when the two ends are tied and cut off short; the serous suture is then carried around the anterior half until it reaches the point where it began, when the two ends are drawn on and tied. The bobbin keeps open the lumen until it is dissolved, and the mucous and serous sutures effectually protect the channel from leakage. If the Murphy button be used, the smallest size is selected and two running sutures are applied. After the gall-bladder has been emptied and the bowel clamped the openings are made in the viscera just sufficiently large to admit the separate ends of the button. The threads are then drawn on and tied around the central barrel of the button, after which the two ends of the button are approximated and pushed home firmly. The anastomosis is then complete. The whole process occupies a very short time and is really very simple; it is, however, necessary to bear in mind that the button has to separate by causing the approximated margins of the openings to slough, and that the true bond of union is only slight at first, so that it is well to keep the patient absolutely quiet for at least a fortnight, lest the new bond of union should give way and permit extravasation of the visceral contents. In considering the question of cholecystenterostomy, it has to be borne in mind that the operation can only be done when the gall-bladder is of moderate size or dilated, and that it is inapplicable to the difficult class of cases where a gall-stone is impacted in the common duct and the gall-bladder is atrophied. When it can be done, the anastomosis should be made to the duodenum, but if preferred a free loop of jejunum may be selected and brought over the hepatic flexure of the colon. In only exceptional cases should the anastomosis be made between the gall-bladder and colon. From a report up-to-date which Dr. Murphy has been so kind as to furnish me, cholecystduodenostomy has been performed with the aid of the anastomosis button in sixty-seven non-malignant cases with only three deaths, these being due to continuous hæmorrhage from laceration of the liver substance on the seventh day, to cholæmia on the fourth day, and to septicæmia on the fourth day, respectively. Of his twelve malignant cases ten died, giving a mortality of 83·3 per cent. My own cases are eleven in number, with one death, and that in a case of malignant disease with long-continued jaundice; my percentage mortality for cholecystenterostomy for gall-stones is therefore *nil*.

Choledochostomy is the term applied to the direct surface drainage of a dilated bile-duct. Terrier has described four cases;[11] I heard of a fifth from Dr. Arnison, of Newcastle, and found a sixth in the Museum of Guy's Hospital, all ending fatally within a few days or weeks of operation, owing to associated choledochitis and infection of the bile channels in the liver itself. In July, 1896, I performed choledochostomy in a man aged twenty-five years, after crushing a gall-stone the size of a small hen's egg, situated at the junction of the cystic and common ducts; the gall-bladder was much smaller than the duct, and I found it easier to fix and drain the duct. The patient made a good recovery (Case 150 on my list). Where it is impossible to clear the ducts, instead of performing choledochostomy, the operation of choledochenterostomy may be done, the union of the dilated duct to the duodenum being made by means of a Murphy's button. I have twice performed the operation, which has also been done successfully by Dr. Sprengal and Dr. Kiedel, and by Dr. Swaine. In my own cases I removed the shrunken and diseased gall-bladder, and fixed the end of the dilated cystic duct to the bowel by a Murphy's button in one case and by a bone bobbin in another. No drainage was employed. The button was voided at stool on the tenth day. In concluding my lectures I must thank you, Mr. President, and my audience for the kind forbearance which you have shown in listening to details which I fear may at times have been somewhat wearisome. My wish has been to show the importance of the subject I have taken up and some of the results which may be looked for by appropriate surgical treatment, and if I have succeeded in exciting your interest and in making it evident that in the greater number of diseases of the gall-bladder and bile-ducts surgical treatment is well worth considering after a fair, though not too prolonged, trial of medical means, my aim will have been accomplished.

ON THE MECHANISM BY WHICH THE FIRST SOUND OF THE HEART IS PRODUCED.[1]

BY SIR RICHARD QUAIN, BART., M.D., F.R.C.P. LOND., F.R.S.,

PHYSICIAN EXTRAORDINARY TO THE QUEEN; PRESIDENT OF THE GENERAL COUNCIL OF MEDICAL EDUCATION, ETC.

IT is a well-recognised fact that the action of the heart is accompanied by the emission of certain sounds, which are described as the first and second sounds of the heart. These sounds, which were observed soon after Laennec had discovered the use of the stethoscope, have been compared to the sounds produced by the utterance of the words "lŭbb-dŭp." They have been studied with interest by the physicist, the biologist, the pathologist, and the clinical physician; by the latter especially, inasmuch as the changes produced by disease in the character of these sounds become of material assistance in the diagnosis and treatment of diseases of the heart. An explanation of the mechanism by which phenomena so distinct, so constant, and so remarkable are produced has been sought for by many observers amongst the classes just mentioned.

The second sound is the result of the sudden tension of the semilunar valves caused by the resistance which these valves offer to the retrograde flow of the blood from the aorta and pulmonary artery respectively into the ventricles on the cessation of systole.

[Sir Richard Quain, after referring to the doubt existing as to the cause of the first sound, continued:—]

It seemed to me to be desirable, amidst such differences of opinion, to solve if possible a problem which has its special interest and its special importance. Two of the most striking events which take place during systole—namely, the closure of the auriculo-ventricular valves and the muscular contraction of the ventricular walls—are regarded by many authorities as the sources whence the first sound proceeds. The result of my investigations, on the one hand, leads me to the conclusion that neither of these explanations is satisfactory; and, on the other hand, enables me to indicate what I believe to be the real explanation of the phenomenon.[2]

A. The action of the auriculo ventricular valves is not the source of the first sound of the heart.—The mechanism of these valves (the mitral and tricuspid) and their action do not possess the elements necessary for the production of such a sound.

[Sir Richard Quain here gave an account of the action of the valves and proceeded:—]

Further evidence on this point may be found in another direction—namely, in the fact that the first sound can be heard independently of the existence and action of mitral and tricuspid valves. Aware of the fact that in some of the lower animals, more especially in the reptile class, the auriculo-ventricular valves exist in but a very rudimentary form, I obtained permission to examine some of these creatures in the Zoological Gardens, and spent many hours on many occasions in the investigation, assisted by my valued friend Dr. John Sibbald.

[Sir Richard Quain then referred to the first sound being audible in the python and the kangaroo—which have only rudimentary auriculo-ventricular valves.]

Objections will, no doubt, suggest themselves to the view above expressed. For example, the clinical physician will say, "I am in the daily habit of hearing a distinct murmur accompanying the systole in cases of diseased heart, and apparently replacing the first sound. On examining the heart after death I find the auriculo-ventricular valves diseased—a condition with which I therefore connect the murmur." It will at once be seen that we have here to deal with morbid sounds, totally different in character and totally different in the seat and mode of production, from the first sound of the heart. To make the explanation more simple I will confine my observations to two principal forms of mitral disease associated with systolic murmur—namely, first, imperfection in structure with distinct regurgitation; and, secondly, induration, roughness, and irregularities on the mitral valve.

[Sir R. Quain described (*a*) the mitral regurgitant murmur, and (*b*) the systolic murmur without regurgitation. He continued:—]

These murmurs, striking and characteristic as they are, are merely accidental complications which occur at the moment of the systole of the heart; but they are unconnected with, and have no relation except in point of time to, the healthy first sound, which may be heard apart from, and independently of, them. The weight of evidence, then, is clearly against the possibility of the structure or the functions of the auriculo-ventricular valves being the source whence proceeds the first sound of the heart.

Two other phenomena occur synchronously with the systole of the heart, and consequently with the occurrence of the first sound. They are (*a*) the contraction of the muscular walls of the ventricles, and (*b*) the propulsion and movement of the blood from the ventricles into the arteries. I shall first consider the supposed share which muscular contraction has in the formation of the sound.

B. The muscular contraction of the walls of the heart during systole is not the source of the first sound of the heart.—The sound produced by muscle during its contraction was first described by Dr. Wollaston.[3] He compared it to "a sound which resembles most nearly that of carriages at a very great distance passing rapidly over a rough pavement."[4] It is very difficult to conceive the slight, soft, rolling sound produced by muscles in action being convertible into the loud, booming first sound of the heart. Yet the theory is accepted. If muscle during contraction could produce so marked a sound, we should expect to find that the powerful muscles of the neck attached to the base of the skull and those attached to the jaw (being through the bones of the skull in direct relation with the hearing apparatus) would give us some striking evidence of the production of muscular sounds when they are thrown into strong action. But there is nothing of the kind. I have failed to hear such sounds when listening to the powerful contraction of the biceps, or on listening to the contraction of the shoulder muscles of a strong cart-horse struggling with a heavy load in ascending a hill. I could hear no other sound save the soft, rolling sound described by Dr. Wollaston. Still, many observers have argued that the contraction of the walls of the heart differs from the action of the skeletal muscles, and that it is this peculiar form of contraction which causes the first sound. They have adduced so many observations in favour of this doctrine that it will be necessary to examine them. But before doing so, for the sake of making my argument more clear, I desire to point out that there is another event which occurs simultaneously with the systole of the ventricle. This is the propulsion of the blood from the ventricles and its impact against the column of blood resting on the semilunar valves. With a view to showing how large a share the sound of muscular contraction has in producing the first sound observers have cut off altogether the supply of blood from the cavities, and on listening during the contraction of the heart have heard a systolic sound. Such were the old experiments of Ludwig and Dogiel, represented as confirmed by Krehl[5] and by Kasem-Beck.[6]

The conclusions which have been drawn from these experiments are disproved by those conducted by my friend Professor Halford, and described in his essay on "The Action and Sounds of the Heart," published by Churchill (1860). He writes: "Large dogs were obtained, and, as in my preceding experiments, the heart was exposed, and the circulation kept up by artificial respiration. A stethoscope being applied to the organ, sounds were distinctly heard. The superior and inferior venæ cavæ were now compressed with a bull-dog forceps, and the pulmonary veins by the finger and thumb; the heart continuing its action, a stethoscope was again applied, and neither first nor second sounds were heard. After a short space of time the veins were allowed to pour their contents into both sides of the heart,

[1] A paper read before the Royal Society of London on June 3rd, 1897.

[2] I have to acknowledge with thanks the assistance rendered me in arranging my notes of this memoir by my valued friend, Dr. Mitchell Bruce, during my recent severe indisposition.

[3] Philosophical Transactions, 1810.

[4] It is interesting to note that Dr. Wollaston, in examining the sound produced by the muscles of his leg, made use of a wooden rod to convey the sound to his ear. He may be thus said, in a measure, to have anticipated the principle of mediate auscultation discovered by Laennec in 1816. The muscular sound which we now recognise is that accurately described by Dr. Wollaston.

[5] Du Bois-Reymond's Archiv, 1889, p. 253.

[6] Pflüger's Archiv, vol. xlvii., p. 53.

Hosted by Google

and both sounds were instantly reproduced. On the veins being again pressed all sound was extinguished, notwithstanding that the heart contracted vigorously. Blood was again let in and both sounds restored. I have thus frequently interrogated the same heart for upwards of an hour, and always with the like result" (p. 25). These experiments of Professor Halford must be accepted as sufficient to refute the view of the German observers just quoted. Another source of fallacy in making experiments of this kind is that a very slight stroke of the muscle or ventricle against the end of the stethoscope is sufficient to produce a very loud and distinct sound, resembling the first sound. If the palm of the hand, for instance, be pressed gently over the ear, and the back of the hand be touched by a finger of the opposite hand, it will be felt how slight a stroke is sufficient to produce a very distinct sound. Observers (Ludwig and Dogiel) have recognised the difficulty of isolating muscle from the instrument conveying the sound, and they have placed the empty heart, still contracting, in a jar containing defibrinised blood or warm water, from the side of which a neck is projected covered by a thin layer of indiarubber. At each contraction of the heart a distinct sound, resembling the first sound of the heart, was heard. But the flapping of the heart against the water was quite sufficient to produce the sound which was conveyed to the ear, and I cannot see in such an experiment sufficient evidence of the sound of muscular contraction being the cause of the first sound of the heart.

Experiments of another kind have been emp'oyed to show that the contraction of the muscle is a source of the sound. Hürthle[7] and Einthoven[8] show graphically that the first sound begins with the very beginning of the systole, before the ventricle has got power "to open the valves." This observation is entirely consistent with the view I am about to propose. The moment the ventricle begins to contract the impact of the blood against the semilunar valves commences, producing the commencement of the sound, not when the valves are thrown open. The valves being connected with the fibroid ring surrounding the base of the heart, with which also the muscular walls are continuous, the sounds are conducted to the apex. Pathology confirms this view. It was observed by Dr. Stokes that in the course of typhus fever the first sound of the heart gradually disappears. After death it is found that the walls of the heart are softened, and this morbid state has been accepted as a proof that muscular contraction is the cause of the first sound. The real explanation is that the impulse of the heart is so feeble that it is unable to produce the sound at the valves. The correctness of this view is confirmed by the fact, recorded by Dr. Stokes, that the last point at which the sound disappears is over these valves, and that it is at the same point that the returning sound is first heard.

With the object in view of further investigating this subject I requested my friend, Dr. Alexander Morison, to study the heart of a turtle recently killed by holding it close to the ear as one holds a watch when testing for deafness, and also by pressing it gently against the ear. With this intention I gave him an introduction to the proprietors of the "Ship and Turtle" tavern, where he had the fullest opportunity of carrying out the investigation. Dr. Morison writes to me: "An opportunity was afforded me of examining the hearts of two large turtles immediately after they were killed. The heart removed from the body was easily provoked into active contraction by a gentle tap with the finger, the contraction being sufficient to expel blood from the cardiac cavity. On placing the ear close to the heart whilst thus contracting no sound could be heard; on placing the ear lightly on the heart whilst contracting no sound could be heard. So far, therefore, as a turtle's heart is concerned—no other that I know of has more vigour of contraction after removal from the body—muscular contraction as a cause of cardiac sound must be excluded." These facts and observations are, in my opinion, sufficient to prove that the contractile action of the muscles of the heart is not capable of producing the first sound of the heart.

Having thus endeavoured to show that the cause of the first sound is independent alike of auriculo-ventricular action and of muscular contraction of the walls of the heart, I proceed to consider a third event, the most striking and important of all those which occur during the systole of the heart—that is, the propulsion of the blood contained in the ventricles into the pulmonary artery and the aorta, and herein to indicate what seems to me to be the agency by which the sound is produced.

C. The first sound of the heart is caused by the impact of the blood driven by the action of the muscular walls of the ventricles against the block produced by the columns of blood in the pulmonary artery and aorta which press upon the semilunar valves.—I would adopt the explanation suggested by my valued friend, the late Dr. C. J. B. Williams, that "sound is a phenomenon resulting from resisted motion." Let us examine the condition of the circulation with regard to this particular point—namely, resisted motion. In this inquiry I have derived most important assistance from the admirable and elaborate researches of Professor Bell Pettigrew, F.R.S., first on "The Arrangement of the Muscular Fibres in the Ventricles of the Vertebrate Heart," published in the Transactions of the Royal Society of London, 1864, and, secondly, on "The Relations, Structure, and Functions of the Valves of the Vascular System," published in the Transactions of the Royal Society of Edinburgh, 1864. These refer especially to the left ventricle, but, at the same time, it is to be observed that what applies to this ventricle applies, only in a lesser degree, to the right ventricle. Professsor Pettigrew explains the manner in which the column of blood, projected from the heart into the aorta, is formed by the union of three columns—an arrangement which results from the mechanism of the heart as fully described by him. These columns ultimately unite into one before reaching the orifice of the aorta. The columns have a spiral motion, which is the result of the spiral arrangement of the musculi papillares, of the spiral arrangement of the fibres composing the walls of the ventricle, as well as of the spiral shape of the left ventricular cavity itself. These points, illustrating the character of the flow of the current, are shown in the blood-cast from the interior of the left ventricle of a horse, which, by permission of the President of the Royal College of Surgeons of England, I am able to submit to examination.

By this spiral, or what might be called "rifle," motion the blood is seen to be directed against the segments of the semilunar valves, which are thereby hastily thrown apart, the spiral current being continued for some distance within the aorta. The beautiful rifle mechanism here described is constructed with the definite objects of giving precision to the direction of the moving body against a given point and of securing greater velocity and force in that body—the moving column of blood. We have, in fact, here represented in nature—a matter of the deepest interest to the biologist—the mechanism of the comparatively modern rifle. The resistance to the stream of blood issuing from the ventricle is offered by the block formed by the column of blood resting on the aortic valves. These in their action are described by Professor Pettigrew as "closed by a spiral movement, by which these valves are wedged, and, as it were, screwed, more and more tightly into each other"; the movement here—the spiral movement—being caused by "the direction of the sinuses of Valsalva, which curve towards each other and direct the blood in spiral waves upon the mesial line of each segment."[9]

We find that various estimates have been given of the absolute propelling power of the ventricles and of the resistance of the column in the pulmonary artery and in the aorta respectively. For example, Professor Michael Foster says: "If we take 180 grammes as the quantity in man ejected at each stroke at a pressure of 3·21 metres of blood, this means that the left ventricle is capable at its systole of lifting 180 grammes 3·21 metres high—i.e., it does 578 gramme-metres of work at each beat."[10] Different estimates of the propelling force are given by physiologists, and the estimates of the resistance vary more even than the estimates of the propelling power. It will therefore suffice to say that authorities are substantially agreed that the driving power and the resistance are in the proportion of 4 to 3, the really important point for our present purpose being the relation they bear to

---

[7] Ibid., vol. lx., p. 263.

[8] Ibid., vol. lvii., p. 617.

[9] Transactions of the Royal Society of Edinburgh, vol. xxiii.

[10] As an illustration of the great mechanical force exercised by the muscular walls of the heart, Professor Michael Foster says that "the work of the whole heart during the day would amount to 75,000 kilogramme-metres, which is just about the amount of work done in the ascent of Snowdon by a tolerably healthy heavy man" (Text-book of Physiology, by M. Foster, M.A., M.D. Lond., 1893). Professor Haughton, F.R.S., in his learned and most interesting work on "The Principles of Animal Mechanics," says that "the daily work of the left ventricle is equivalent to lifting 89·7 tons through 1 foot" (Longmans, London, 1893).

Hosted by Google

each other. In the motion thus described and the resistance we have all the elements for the production of a sound; and a sound being produced, we ask what it is. The reply must be: the first sound of the heart, the cause of which we now seek.

If it be admitted that sound is a result of resisted motion we have in this instance a remarkable illustration of movement and resistance. The movement of the blood with all the force, precision, and velocity of a rifle or spiral movement is directed against a fixed and definite resistance, the moving power and the resistance being capable of definite measurement and found to be quite sufficient themselves to explain the source of the sound of which we are in search. This explanation was first suggested to my mind many years ago by the occurrence of a case of disease in which the aortic valves, being completely broken down by disease, became inadequate to their function. A murmur of such intensity was produced that it was audible at two or three inches from the wall of the chest without any intermediate communicating body. With a view to determine how far this murmur might be conducted along the course of the circulation I examined the femoral artery. There I found that the murmur was not conveyed to the ear, but a sound precisely resembling the first sound was heard—a sound caused by the pressure of the stethoscope resisting the motion of the blood in the artery, which, the valves being destroyed, thus received the full force of the ventricular contraction. My attention was thereby directed to the obstruction offered by the aortic valves in health to the blood in leaving the ventricle. I felt the case to be so interesting that I submitted it to a meeting of the Harveian Society, and my observation is recorded in the minutes of the meeting, April, 1852. From that time to the present I have taken every opportunity of investigating the subject. Observations have been made on the course of the circulation in the femoral artery under like circumstances by Duroziez, Moulie, von Bamberger, and others. These observations, however, have had reference more especially to the diagnosis of disease of the aortic valves, and I mention them here only as indicative of interesting investigations having been made on the femoral artery in cases of diseased aortic valves. The observers named make no special reference to the first sound of the heart in health.

Objections may be offered to the explanation of the first sound of the heart here brought forward, founded on the fact that this sound is heard more distinctly at the apex of the organ, a point removed from the seat of the valves. The observation is perfectly correct, but the explanation is simple. The muscular walls of the heart are connected, as above described, with the fibroid ring which is intimately associated with the semilunar valves. The sound produced at these valves is communicated to the apex of the heart through the fibroid ring and the muscular walls, which at the moment of systole are tense and firm. The sound thus conducted reaches that portion of the heart which is uncovered, and which is in contact with the walls of the chest. But, on the other hand, when opportunity offers it has been found that the sound in question is heard over the aortic valves more distinctly than in any other situation. A remarkable case of this kind has been related by M. Cruveilhier, who was invited to see an infant just born presenting a complete case of ectopia of the heart. He says: "On examining the heart thus exposed both sounds were distinctly heard over the base, and *not* at the apex." He remarks: "We must not forget that one element of the sound, that produced by the shock of the heart against the chest-wall, is absent." [11]

Another point of interest is that which has already been alluded to in the case of typhus fever, as described by Dr. Stokes—namely, that the sound disappears last over the semilunar valves, and also that the returning sound is first heard in the same situation. It is also an object of great interest to compare the characters of the two sounds in relation to the seat of their origin at the semilunar valves. In the first sound we have the character of propulsive force and sustained action, softer and more prolonged than the second sound, which is sudden, sharp, and short, as if produced by an abrupt mechanical disturbance. These distinctions, which may be readily recognised in various degrees by careful observation, serve to convince us that the sounds are both produced at the same point—at the semilunar valves, each by its own single and simple agency.

[11] Gazette Médicale, 1841, p. 488.

D Lastly, sounds resembling the first (and second) sound of the heart can be produced artificially in accordance with the view contained in the preceding communication.—The experiment is thus made: a sheep's heart of good size (or that of a calf) may be used. It must be carefully cleared from pericardium, leaving the large vessels and pulmonary veins as far as possible intact. The orifices of the pulmonary veins must be laid into one, so as to permit a sufficient opening into the left auricle through which to divide the attachments of the mitral cusps and the musculi papillares in the left ventricle, taking care in doing this not to injure the aortic segments when detaching the cusp that lies next them. The coronary artery must next be ligatured, and also the innominate artery where it springs from the aortic arch. The right auricle and ventricle should be removed. Through the opening made by laying into one the orifices of the pulmonary veins a bone nozzle should be passed. It is well, also, to ligature the auricular appendix and any points from which water may issue when the ventricle is filled. To the posterior orifice of the nozzle rubber tubing should be attached, communicating with a source of water-supply, placed on a higher level; and another portion of rigid guttapercha tubing, about three feet long, should be introduced into the aorta. If, now, the ventricle be filled with water by means of the tube in the left auricle the water will of course pass into the ventricle and thence up the aorta, a portion of the water resting upon and closing the aortic sigmoid valves.

If, further, the ventricle be compressed periodically in imitation of systolic contraction, and allowed to relax in imitation of diastolic relaxation, a sound closely resembling the first sound of the heart will be produced when water is propelled from the ventricle into the aorta, and another closely resembling the second sound when propulsive movement ceases, and the sigmoid valves again close under the superincumbent weight of water in the aortic tubing. As the fluid rises in the guttapercha tube the pressure on the valves increases and the sound becomes more marked; when the fluid, on the other hand, diminishes the sounds become less distinct. If the heart be placed horizontally the sounds become wobbly. The terminal piece of small diameter of a binaural stethoscope gently placed over the aorta at its commencement is most suitable for observing the cardiac sounds in this experiment.

The experiment here described, when first suggested by me, was submitted, with the assistance of Dr. Sibbald, to my lamented friend, the late Dr. Sharpey, and to Sir James Paget, who were quite satisfied that with the increase or diminution of the column the sounds closely resembled those of the heart in man, and that they became more or less distinct in proportion to the quantity of fluid contained in the tube.

In conclusion, I may say that I was moved to undertake and continue this inquiry by a desire to obtain a solution of what seemed to by an insolvable problem, and also by a belief that a correct explanation of the cause of the first sound of the heart would be of practical value in the study of the clinical phenomena of diseases of this organ.

I would wish further to add that the explanation of the cause of the first sound of the heart given in this communication being so different from that hitherto accepted may seem calculated to create difficulties in the diagnosis of valvular disease of the heart. Closer consideration will show, however, this not to be the case, but that, like all accurate knowledge, it will be found to simplify and not to confuse. It will afford an explanation of the relations of certain morbid phenomena which are at present unintelligible—such, for example, as that a systolic murmur may be heard at the apex whilst the first sound is audible at the base free from murmur; and it will serve to encourage a closer study of the relation between muscular contraction of the walls of the heart and the tension of the vessels of the system.

Harley-street, W.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The new convalescent home at East Finchley was formally opened by the Duchess of Albany on Wednesday last. The home is designed for certain cases of epilepsy, hysteria, and kindred affections in women and children. The old home was quite inadequate, and the present country branch is a necessity for the successful treatment of a large number of the patients who are now admitted to the hospital in Queen-square. The new home, which contains forty beds, has been built and equipped at a cost of £10,000.

VESICO-VAGINAL FISTULA; WITH A DESCRIPTION OF A NEW METHOD OF OPERATION.

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

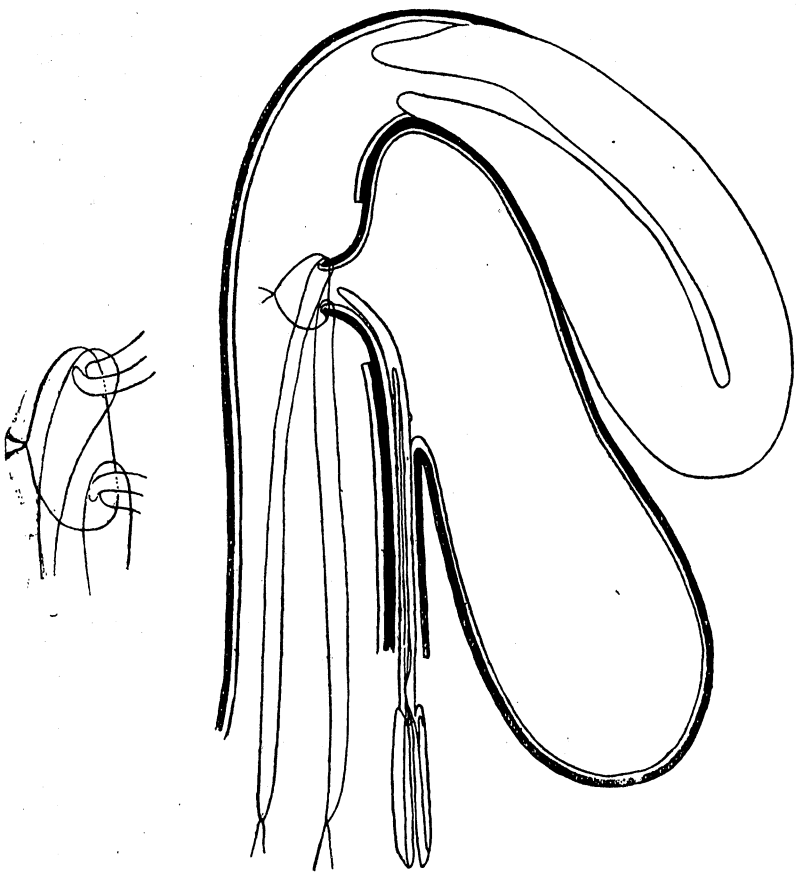
THAT operations for the cure of vesico-vaginal fistula are even now sometimes futile will, I believe, be admitted. Even in the latest list of any importance—that of Milton of Cairo—out of 79 operations 41 were useless. Patients were cured after one operation in 21 instances, after two in 10 cases, after three attempts in 6 cases, whilst 1 case required four operations to effect a cure. In 12 cases no benefit at all was obtained. The lesion is one which is situated in an awkward position for operative work, and one surface at least of the tissue involved is constantly bathed by a fluid which, when it is no longer confined to its own territory, can become very acrid and damaging. Any union which depends for its success upon primary adhesion, if exposed to the action of this fluid, will be extremely likely to break down and allow percolation through into the track of the sutures, and consequent failure. It is necessary, also, with a view to future comfort, that the re-formed bladder should be lined entirely with mucous membrane, any raw surface left being a constant menace, as forming a nidus for the deposition of calculous material. Nothing can be more discouraging to the patient or more exasperating to the surgeon than to see urine once more escaping per vaginam after a tedious and painstaking effort to close the leak. And yet, if the patient determines to leave matters *in statu quo*, she condemns herself to a most miserable existence, the object alike of pity and disgust to all her friends.

Anything like success in the treatment of vesico-vaginal fistula would appear to be a matter of comparatively recent history. Sir James Simpson, writing in 1859, says: "With others I used to regard a patient afflicted with vesico-vaginal fistula as a case generally beyond all relief and all hope." Cumin in 1824 says: "The hopeless nature of these fistulæ is generally acknowledged, and by many they are at once abandoned as incurable"; and Richerand declared that frequent ablutions and a urinal were the *only* means calculated to diminish the trouble inseparable from this disgusting infirmity. And although, as Milton's list shows, present results are not all that could be wished, there has, curiously, been little alteration in the mode of attack by the surgeon during the past fifty years. If the later writers, as Clifford Allbutt and Playfair are consulted, it will be found that all the operations mentioned date back many years, and that in all the edges of the fistula are, without exception, the parts attacked. That they shall first of all be made raw is the essential preliminary, whether the paring method of Sims, Bozeman, Simon, and others, the splitting method of Langenbeck, Collis, and Tait, or the elytroplasty of Jobert and Milton be adopted; the various paring methods differed only in the various angles which the pared surface bore to that of the bladder, the importance attached to preliminary preparation of the patient, the use or non-use of clamps to hold the ends of the stitches or to regulate the position of the flaps, the material of which these stitches were composed, and the position of the patient during operation. The splitting method was the same, whether practised by Langenbeck, Collis, or Tait, and consisted in the splitting from the edge outwards of the tissue between bladder and vagina, so as to obtain a large raw surface at this point. Elytroplasty supplied flaps from various parts of the surrounding tissue, but to fix them in place it was first of all necessary to pare the edges of the existing opening and to fit and suture the raw edge of the flap to these.

The only operation which did not interfere with the integrity of the fistulous edge was the method of desperation, that of kolpocleisis, which transformed the upper part of the vagina into a portion of the urinary reservoir, preventing any escape of the menstrual fluid except through the bladder, and might have been expected effectually to prevent further pregnancy. A case is, however, on record in which this unexpected occurrence actually happened, coition having probably taken place through the dilated urethra. It may be accepted, then, that except in those cases in which any return to the *statu quo ante* is given up as hopeless, the one subdominant idea in the minds of all surgeons who have attacked these cases has been the absolute necessity of a raw surface at the edge of the fistula as the essential preliminary. But is this so essential? Could we not by any means transform this obstacle, on the removal of which surgeons have expended so much time and ingenuity, into our greatest help towards success?

In describing what I think is a novel method I wish to be understood as referring simply to vesico-vaginal fistula, and not to vesico-uterine fistula, although it is suitable for those in the anterior fornix as well as for those lower down in the anterior wall; practically but little is lost by this, since Neugebauer estimated the cases of fistula involving the cervix as only forming 8 per cent. of the whole number, and Hermann and others have pointed out that in the most frequent class, that produced by prolonged pressure of the child's head upon the maternal tissues, the head rarely becomes impacted until after the cervix has dilated and retracted. So far as other causes, such as removal of calculus through the vagina, pressure of impacted pessary, traumatic injury to prolapsed and distended cystocele, as in a case of Kynoch's, go, these will all act on the vaginal wall alone.

During the last two years my attention has been directed to the subject of fistula generally, and especially to the often unsatisfactory result of the usual operation for fistula in ano. It occurred to me that if it were practicable, good results might be expected from separating the fistulous tube as a whole from the tissues around up to, but not through, its connexion with the rectal wall. Sufficient of this tube should then be removed to leave a projection which could be inverted like a glove finger by means of threads attached to its distal periphery and passed through the fistula into the dilated rectum; by pulling upon these the fistulous tube might be inverted into the rectum and fixed by tying a ligature around it just above the level of the bowel wall. What had been its raw outer surface would now be its inner and might be expected to unite with rapidity, whilst the raw surfaces left outside might be immediately united by sutures. The prolapsed inverted tube might then be partly cut away inside the rectum and the ligature left to cut through the remainder, which would not be likely to happen before the outer structures were solidly united. So far I have not been successful, partly because of the action of the sphincter, but mainly because the fistulous track is very seldom a single tube, but usually burrows in various directions. But neither of these objections hold good with reference to vesico-vaginal fistula. Here we have a short straight track, and if there are muscular movements in the tissues around they are more under control, and will be of importance only if there is coincident tension. The tube, however, as it exists, at first sight would be far too small to have any appreciable effect in stopping the gap; but if, instead of looking upon the edge of the fistula as the limit of our available tissue, we regard it simply as a hinge upon which a tube of mucous membrane taken from the vagina and spreading outwards may be made to turn, we have at once at our disposal as much as may be necessary to close any but the most extensive gaps. Both bladder and vagina are lined by the same kind of tissue, mucous membrane, and it is the continuation of this over the edges of the rent which has been heretofore the greatest trouble. Supposing exception to be taken to this, and the edge be looked upon as scar tissue pure and simple, still it is the same tissue as that which it is intended to form by any of the other operations, with the cardinal advantage that it is old and tough, and has passed beyond the dangerous stage in which absorption of deleterious matters is possible.



It is clear that it is the re-formation of the bladder which is the essential point. The union of any raw surfaces in the vagina, although important, is of but secondary importance except so far as it may support or strengthen the re-formed bladder wall. If, then, we utilize the vaginal mucous membrane, not as Jobert or Milton, by displacing it as a flap with two raw edges, which require suturing to the equally raw edges of the prepared fistula, with a granulating surface exposed to the action of urine, but with the mucous surface turned towards the bladder cavity, where alone that kind of surface is of primary importance, and with no break in the edges at all, but making a perfectly continuous surface up to a narrow point of union, we shall have gone far towards solving the problem, and the loss of material in the

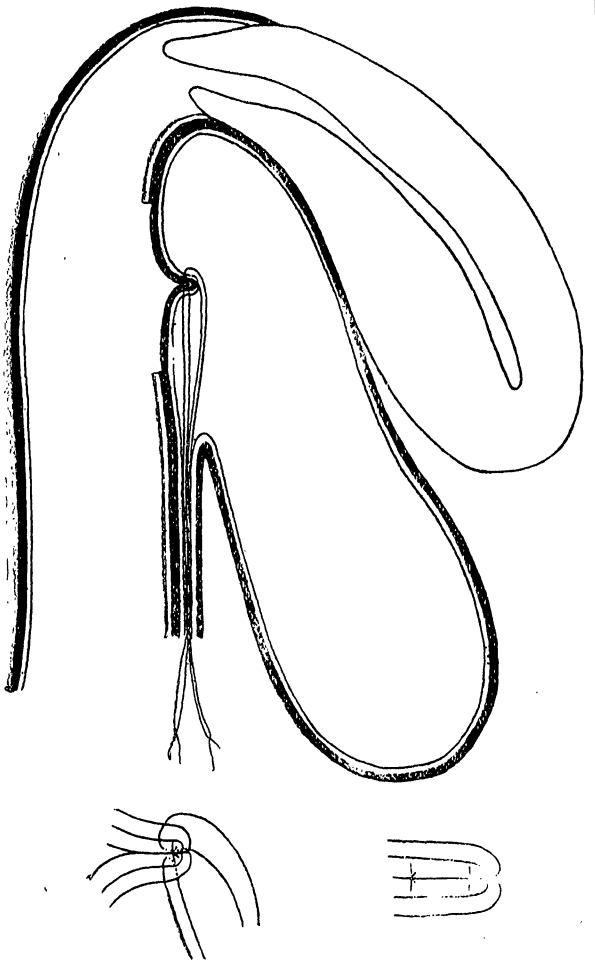
Hosted by Google

vagina will be of very little consequence compared with the advantage obtained.

Acting upon these ideas I suggest, and have carried out with immediate success, the following operation. I pass over, as understood, the extremely necessary preliminary preparation of the patient. The accompanying diagrams will make clear the steps of the operation and the idea of it almost without description. In Fig. 1 it will be seen that a circular incision has been made

FIG. 1.

The flap has been separated and turned into the vagina; two guiding threads are shown in position and the first uniting thread, which passes only around through the connective tissue and muscular coat avoiding the mucosa. A pair of bent forceps is passed through the urethra, its point entering the vulva through the fistula. The guiding threads will be turned up into the vagina and their knots placed between the jaws of the forceps.



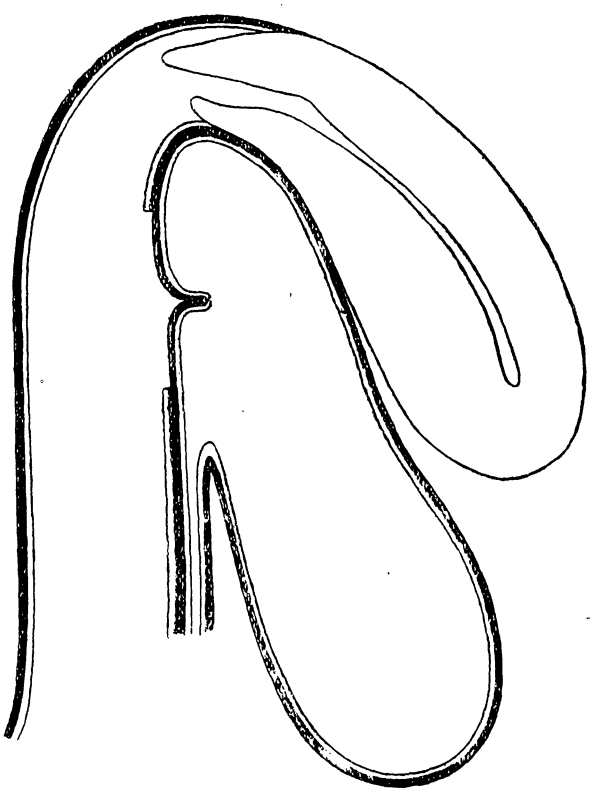
around the fistula, passing through the mucous membrane and part of the subjacent tissue, so that a continuous flap of sufficient thickness can be raised and separated up near to, but not through, the angle at the fistulous edge; the width of this flap must be judged by the surgeon in each particular case. It must, however, be wide enough, when brought together in the way to be described, not merely easily to close the opening, but to project for about a fourth to third of an inch into the bladder cavity at the centre. When so separated it lies like a truncated glove finger attached solely at the edge and continuous with the mucous wall of the bladder. To four equi-distant points in this frill four long double threads are attached, but not knotted, so that they will easily pull out. Each pair is knotted at their ends outside the vagina. Of course, in a section such as shown only two of these double threads can be indicated. When this is done a curved pair of forceps is passed through the urethra until its beak appears in the centre of the frill, the four pairs of threads are brought together, and their knotted ends placed within the grip of the forceps. As this is withdrawn, closed, it will carry the threads through the fistula, through the bladder, and out through the urethra. Gentle traction upon these (see Fig. 2) will invert the circular flap into the bladder in such a way that mucous membrane will face the bladder, whilst the raw connective tissue, surface will face itself and come easily together at the level of the bladder-wall, whilst the innermost edges project as a tube into the bladder cavity; the advantage of this will be shown directly. Whilst traction upon these threads is very gently but firmly maintained, and before the frill is inverted, a fine silk suture is carried round it just above its extremity, the suture passes through the connective tissue, but carefully avoids the mucous membrane. (Fig. 3, enlarged detail). It lies like a purse-string, and it is tightened up just after the inversion takes place. It draws together the raw surfaces of what before inversion was the outer, but is now the inner surface of the frill, and closes the upper extremity of the tuft. When knotted, the ends of this suture are cut off short, and the whole suture is buried by the further inversion produced by a continuance of the traction upon the guiding threads. As soon as this inversion has been carried to such a point that the surfaces of the flaps lie easily in apposition at the level of the bladder-wall another circular suture is applied in the same way and knotted, the ends being cut off. In small fistulæ only one of these sutures may be required; that should always be the one at the level of the bladder-wall. The guiding threads are now divided and drawn out through the urethra, leaving the base of the bladder re-formed (see Fig. 3). As is well known, divided mucous membrane tends to curve over its raw edge. When, therefore, the first suture is tightened the upper surface of the tuft will present nothing but mucous membrane. Fig. 4 shows the appearance of the fistula from the vagina at this stage. The raw surfaces in the vagina, if sufficiently small to be drawn together without tension, are now united by silkworm gut sutures, the ends of which are left long to permit of easy removal. If, however, any tension is likely to be produced, it is better, I think, to apply at once a Thiersch graft taken from some non-hairy portion of skin. This is covered by oiled silk or gutta-percha tissue, and carefully pressed into position. I find careful packing of the vagina with iodoform gauze better than sutures to fix this in position. The patient is made to lie upon her face for ten days, and the catheter is used every two hours the first three or four days.

The advantages I conceive to be obtained by this method are:—1. There is no tension upon the uniting surfaces. 2. Mucous membrane is opposed to the action of urine—that is to say, the contents of the bladder find themselves in contact with the kind of tissue to which they are normally suited and accustomed. 3. The cubic capacity of the bladder is not greatly decreased, as is the case after most of the other operations, but is left normal; therefore, the resulting cure is not discounted by persistent frequency of micturition in after life. 4. The uniting sutures are separated from the contents of the bladder by the entire thickness of the mucous membrane. 5. The uniting surfaces are also thus protected; with the patient on her face, if any urine is projected against the tuft it will drip from its outer layer, which is mucous membrane. 6. Should the ureter be exposed at the edge of the fistula, or should its orifice, which happens in most cases, be near it, it will not, as in the old operation, discharge right on to the line of union, but into a gutter formed of mucous membrane, which cannot be damaged by such discharge, and it will also be noted that it is impossible for the ureteral canal to be compressed by a wrongly-placed stitch, fixed in the middle of the scar, or left outside the re-formed bladder—it must necessarily be

Hosted by Google

turned in by the flap thus formed and left in a safe position. 7. In old cases—where, especially, freedom from muscular traction is of most importance—we are provided with a natural replica of Simpson's splint in the tough edge of the fistula, now surrounding the uniting tissues, all the

FIG. 2.



In Fig. 2 the guiding threads have been drawn through the urethra pulling the circular flap or frill into the bladder. The first uniting thread has been drawn tight and knotted, closing the upper extremity of the frill. This is shown also in enlarged detail. The two uniting threads are shown tied, and the frill thus closed above and below.

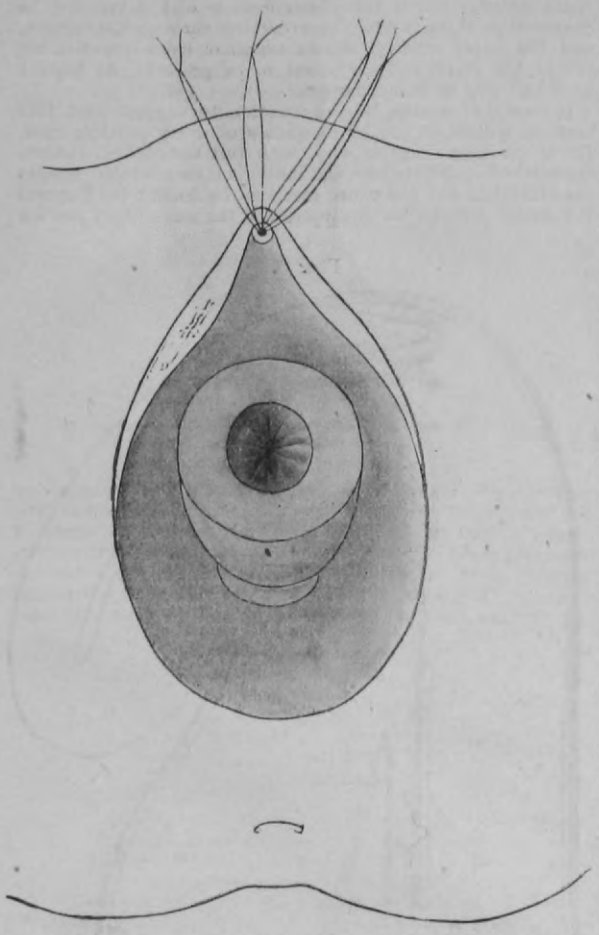
more effective because it is situated in the tissues themselves. This is another instance of the way in which the altered conditions produced by the operation transform the previous obstacles to success into distinct advantages.

Since this paper was written my attention has been called to one by Professor Ferguson, of Manitoba, in the *American Journal of Obstetrics*, and it is evident that the principle of reversal of mucous membrane from the vagina, which I thought had been original, has been anticipated by him. His operation, however, is otherwise quite different from the one I have described, and does not, I submit, appear calculated to gain all the advantages which are possible. Professor Ferguson separates the mucous membrane of the vagina in much the same way as I have shown, but he makes his flaps only large enough to meet one another easily on a level with the floor of the bladder. They are united in that position by a continuous suture, avoiding the mucous membrane so as slightly to invert the line of union. There is no attempt to pull them inwards into the bladder or to agglutinate them together into a tuft. In all cases the vaginal wound is directly united by interrupted sutures. It appears to me that, first, the resulting line of union will be practically on the same plane as that of the bladder wall, therefore the amount of uniting surface will be much less, consequently the risk of yielding, both immediate and secondary, will be much greater. And most of all, the discharge of urine from the ureters will play directly upon the uniting edges and may very easily contaminate the sutures. As Simpson said in criticising the operations of his day: "There is the danger of infiltration of urine between the raw lips of the wound on the vesical side, provided the internal surfaces of the lips are not entirely closed, which they can scarcely in all cases be expected to be, by the sutures employed." Perhaps the difference between the two operations will be even more clearly apparent if I refer to a kindred condition, differing mainly in position. In supra-pubic cystotomy, when for some reason the bladder has not been immediately closed, a time will come when the opening is no longer required and closure is desired. Closure will here sometimes occur from simple cicatrisation, but now and then it does not. If the bladder-wall be separated from the abdominal, the edges of the opening in the former pared and simply brought together by sutures, one often fails to get primary union, and leakage again occurs; but if the circumference of the opening be drawn in by threads which are carried through the urethra, and the outer surface drawn together by a purse-string suture, the result will be found to be perfect. At least, I have had that double experience.

It would, of course, be presumption to suggest that this method will meet the requirements of every possible case. He is the best surgeon who, with full knowledge, chooses the method best fitted for the individual case which engages his attention, but the more methods he has at his disposal the better will he be equipped and the more likely are his

FIG. 3.

The guiding threads have been divided and withdrawn, leaving the base of the bladder re-formed with no threads exposed to the action of the urine.



efforts to be crowned with success. The following cases show the result so far obtained. It will be noted that in all there was never the slightest leakage from the time of operation.

CASE 1.—A medium-sized woman, aged thirty-one years, was admitted to hospital on Sept. 22nd, 1896. She had had two children. In the case of the first—who was at this time ten years old—labour was easy, and there were no after-effects. The second was a six months

Hosted by Google

dead child. Labour was tedious and was terminated by instruments. The patient had no difficulty with the urine directly after her confinement, but about a fortnight after she first noticed urine trickling from her vagina; this had become much worse lately. She was in bed for three weeks after confinement with, she says, rheumatic fever. In front of the cervix and about half an inch from the vaginal reflexion was an opening which admitted barely two fingers. The opening was smooth and the edge thin. The vagina was slightly excoriated, but there were no deposits. The urine was of specific gravity 1015, acid, and with a very faint trace of albumin. After careful douching, &c., the vagina appeared to be healthy. On Oct. 6th the operation was performed with one purse-string suture. The vaginal wall was united by interrupted silkworm gut sutures. The patient was placed on her face. A catheter was inserted and kept *in situ*. The vagina was irrigated daily with

FIG. 4.

Shows the appearance of the re-formed bladder from the vagina. The guiding threads are shown issuing from the meatus.

boracic solution. There was no leakage after the operation. On the 17th the vaginal sutures were removed and the wound healed. The patient could pass urine herself. On the 29th she was discharged, when she could hold urine six hours easily.

CASE 2.—The patient was a tall, masculine looking woman, aged twenty-eight years, with a flat pelvis. She had had one confinement, which lasted two days and was terminated by craniotomy, which occurred one year previously, when she was five weeks in bed. She had noticed a leakage before getting up. On Nov. 3rd, 1896, the opening admitted two fingers easily; the vagina was tender, somewhat raw, and encrusted in small patches. The urine was slightly alkaline and of specific gravity 1016. By the 20th careful nursing and the use of salol and mineral acids with local treatment produced a fairly healthy vagina, with acid urine, and the operation was performed with two purse-string sutures. A graft was taken from the thigh below the trochanter. The vagina was packed with iodoform gauze. The patient was placed on her face and the catheter was passed every two hours. There was no leakage of urine. On the 23rd some gauze was removed and the vagina was repacked. On the 26th there had been no leakage and all the gauze was removed. Almost all the graft had united, except at one side. This was sloughing and nearly separated, and was cut away, leaving a raw space measuring one inch, which was, however, cicatrising. Douching was performed daily with boracic solution which was followed by insufflation of dermatol. On the 30th there was still no leakage. The patient had passed urine herself. She was not allowed to hold it for more than four hours, but she could do so. She was placed on her back. The vaginal wall had nearly healed. On Dec. 10th the patient was allowed to go home. There had been no leakage. She could hold urine for six hours. The vagina was perfectly healed and felt supple. The grafted patch felt somewhat thinner and smoother than the remainder, but there was no bulging.

CASE 3.—A medium sized woman, aged forty years, married at the age of thirty-five years, had had one child seven months previously to coming under my notice. The labour was tedious, but no instruments were used. A leakage was found on the fifth day. Convalescence was slow. There was no fever. The patient had undergone one operation by another surgeon, but the leakage returned; she was not sure how soon after, but thought that there was some during the first week. On Jan 2nd, 1897, there was an opening of the size of half-a-crown in the anterior wall near the centre, the edges of which were scarred. The patient was very cleanly and the vagina was only slightly sore. The urine was acid, of specific gravity 1020, and there was no albumin or sugar. On the 5th the operation was performed with two purse-string sutures. The vaginal edges were approximated with silkworm gut, two lateral incisions being made to relieve tension. She was placed on her face. Daily douching was performed after the first four days, during which the vagina was lightly packed with iodoform gauze. The catheter was used every two hours for two days, after which she passed urine naturally, but was not allowed to hold it for more than three hours at a time. On the 20th the vagina had healed. The suture was removed on the 13th, and the patient has had no leakage since the operation.

Manchester.

A CASE OF

ADDISON'S DISEASE IN A CHILD TREATED FOR A FEW DAYS WITH SUPRARENAL EXTRACT WITHOUT BENEFIT; CHARACTERISTIC LESIONS FOUND POST MORTEM.

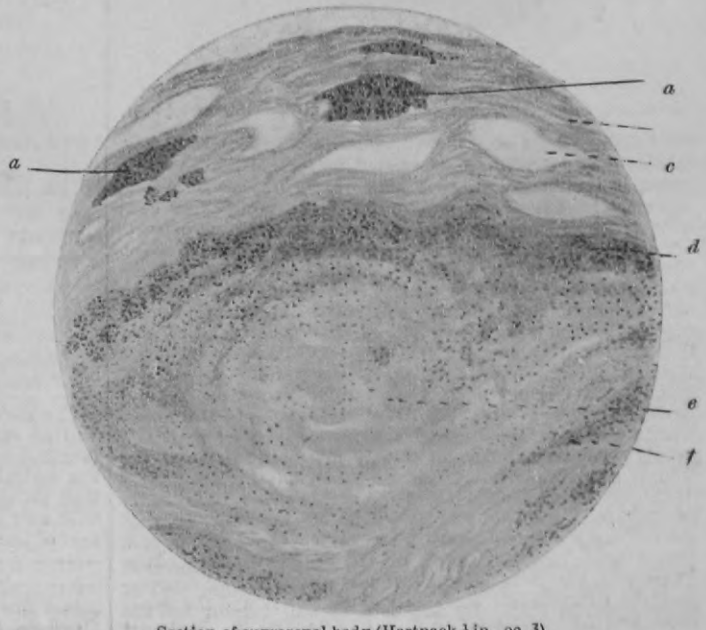
BY JUDSON S. BURY, M.D. LOND., F.R.C.P.,
SENIOR ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

THE following case is noteworthy on account of (1) the early age of the patient—Addison's disease being exceedingly rare under the age of fifteen; (2) the history of a temporary discolouration of the skin occurring one year before the onset of the definite symptoms of the disease; and (3) the family history of phthisis and of brain disease. As regards the treatment of Addison's disease some recently reported cases strongly suggest that an extract of the suprarenal capsules may prove to be of great service. Many of these cases are reviewed by Dr. Ringer and Dr. Phear in a paper published in the Transactions of the Clinical Society for last year. They record a case of their own in which temporary improvement followed the administration of suprarenal extract; the pigmentation diminished in intensity and the patient became brighter and stronger.

A girl, aged thirteen years, was admitted under my care at the Manchester Royal Infirmary on June 6th, 1896. Her mother told me that she was always a delicate child, was easily tired, and always seemed to be very sleepy. When an infant she attended a children's hospital for rickets and diarrhœa, but did not suffer from any other definite illness before the present one. She had never had a severe fall or

Hosted by Google

received any bodily injury. About two years ago she stayed for two or three weeks with some friends at Alderley Edge. On her return to Manchester it was noticed that she looked dark coloured, as if much sun-burnt. The neighbours said "If she had stopped there another week she would have been quite black." "Her body was brown all over." But in a few weeks she became a natural colour again. The present illness began about twelve months ago with symptoms of gastric disturbance; thus "she could not take her food properly; it turned on her stomach, and she began to vomit." Sometimes she vomited several times a day. She also suffered from severe headache. On three occasions she fainted. A few weeks from the commencement of her illness a change in the colour of her skin was noticed, and it gradually became darker. The schoolmaster used to send her home from school because she had not washed herself properly, and the patient used to cry when she got home, saying, "I had washed myself." She left school on Jan. 20th—her thirteenth birthday. During the last two months she vomited every other day, and gradually became weaker. She was the eldest of a family of ten, of whom four other children were living and well. The others died in infancy—one from whooping-cough and convulsions, another from convulsions, another from "dentition," another from hydrocephalus, and another from congestion of the brain. Her mother's sister died at the age of thirty-five years from phthisis, and a sister of her father died aged thirty-one years from epilepsy, dementia, and phthisis. On admission she was found to be a thin, slenderly-built child, and had obviously wasted to a slight degree. The discolouration of the skin was the most striking feature; she looked like a Mulatto, all parts of the surface of the body being of a brown colour. The tint varied in depth in different parts, but the transition between a dark brown and a light brown was everywhere quite gradual. The bronzing was most intense at the back of the neck, on the dorsum of the hands, on the lower part of the abdomen, and over the knees; it was least intense on the palms of the hands, the soles of the feet, and over the calves of the legs. No pigmented moles could be found. The nails were of normal colour and the conjunctivæ were pearly white. A faint, patchy pigmentation was seen on the mucous membrane of the lips and the inside of the mouth. The tongue was free from discolouration. No enlarged glands could be found and nothing abnormal could be detected on a careful examination of the chest and abdomen. She complained of pain in the epigastric region, which was worse after food. There was slight tenderness on pressure over each lumbar region, and palpation set up tonic spasm of the abdominal muscles. The spine was free from pain and tenderness. The pulse was 96, regular and feeble. The urine was acid and free from albumin and sugar. The patient was able to walk, but her appearance and action exhibited great feebleness. There was no paralysis and no alteration of cutaneous sensibility. The knee-jerks were increased and the wrist-jerks appeared to be unduly irritable; there was no ankle clonus. The superficial epigastric abdominal and plantar reflexes were exaggerated. She was ordered a bismuth and soda mixture and on June 9th half a tabloid of suprarenal extract to be taken three times a day. On June 16th a freshly made extract was substituted for the tabloids; suprarenal capsules from the sheep were pounded up in a mortar with glycerine in the proportion of one capsule to a drachm of glycerine, and a teaspoonful of the mixture was given three times a day. Since admission the patient had often vomited and no improvement could be noted in her general condition. On June 17th she became decidedly worse, and the pulse was only just perceptible. At 4 30 on the morning of June 18th she had a convulsion and became unconscious. At 10 A.M. she lay with her eyes half open in a state of deep coma; no pulse could be felt at the wrist, and the heart sounds were almost inaudible. The respirations were about 36 to the minute and irregular in rhythm, and inspiration was accompanied by gaping movements. She died at noon.



Necropsy. — At the necropsy made by Dr. Kelynack on the following day the suprarenal capsules with adjacent portions of the spleen, liver, kidneys, and other tissues were carefully removed for subsequent dissection and examination. But few changes were found in any of the other organs. The membranes of the brain were unduly congested; several hæmorrhages were found beneath the visceral layer of the pericardium; there were some slight pleuritic adhesions on the left side of the chest but none on the right side. The bronchial and other glands were normal and no signs of tubercles could be found in the lungs or other organs. The thyroid gland was smaller than natural, but otherwise normal. The abdominal cavity did not present any abnormal appearances, and the spleen, liver, kidneys, stomach, and

Hosted by Google

intestines looked quite healthy. The adrenals were enlarged and firm and adherent to the surrounding tissues.

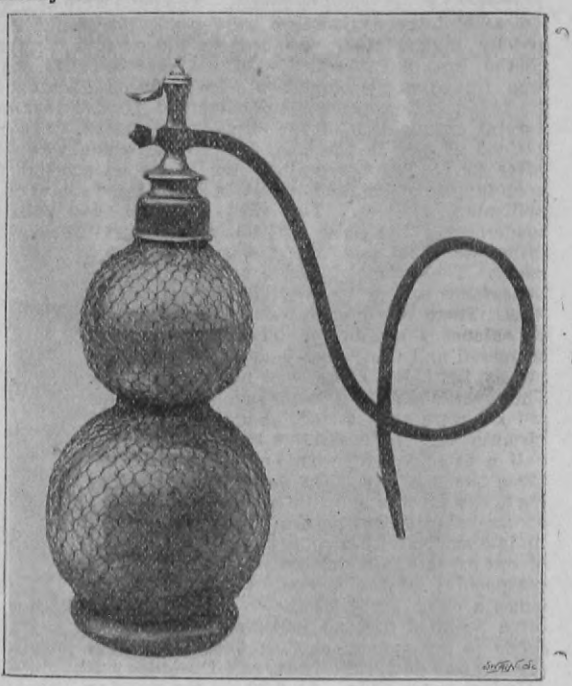
For the following report and accompanying drawings I am indebted to my friend Dr. W. E. Fothergill: "The right and larger body had the usual cocked-hat shape. A piece of diaphragm was adherent to one end of it; also several flakes of fat. Its length was 6·5 c.m., its breadth 1·5 c.m., and its depth 2 c.m. The coverings of fat and connective tissue were closely adherent to the organ, so that no definite fibrous capsule could be found. Transverse sections did not show the usual differentiation into cortical and medullary portions of tissue. The organ was rather seen to be composed throughout of irregular septa of fibrous tissue which separated masses of light colour and caseous consistency. There were cavities centrally placed in several of these masses. The left and smaller body was less regular in shape than its fellow, being thicker and deeper at one end than at the other. It still, however, would be recognisable as a suprarenal body. Its length was 4 c.m., its breadth 1·2 c.m., and its depth 1·5 c.m. Splitting it from end to end, it gave tough resistance to the knife, and a distinctly gritty feeling was recognised in parts, which on subsequent examination were found to be calcareous. The structure was altered just as in the other body, there being no cortex or medulla visible, but irregularly distributed caseating masses of varying size separated by fibrous septa. (See Fig. 1.)

Microscopical examination.—"Slices of both bodies were hardened and cut by the paraffin method, the celloidin method, and the combined method. The inspection of these showed both bodies to be in an exactly similar condition. As regards the characteristic structure of suprarenal bodies, the condition was as follows: The capsule was thicker and denser than usual, and contained numerous blood-vessels.

FIG. 3.

An island of unaltered cortex—a portion of Fig. 2, *a* (Hartnack ⅓ in.).

The cortical layer was recognisable only in a few places, notably in small islands surrounded by fibrous tissue, which lay round the margin of the organ embedded in the thickened capsule. In these islands were groups or columns of cells lying packed together in the interstices of a delicate fibrous stroma. They had large round nuclei, which stained deeply with hæmalum. The cell outlines were faint. There was no trace of the medullary layer, or of the vessels or nerves supplying the organ. Thus within the thickened capsules all the tissues were altered. In the centre of each of the masses of caseating matter was amorphous débris staining faintly with eosin or picrocarmine (Fig. 2, *e*), around this was more débris, staining more darkly and having scattered through it the nuclei of the cells characteristic of the cortical zone. These nuclei stained deeply with hæmalum, and closely resembled those in the islands of normal tissue. Round this band of incompletely destroyed tissue was a layer (Fig. 2, *d*) in which fairly healthy cells were crowded very closely together, so that their deeply stained nuclei gave under the low power a purple zone round the pink of the débris in the centre. There was, however, no trace of the characteristic arrangement in columns of these cortical cells. Round the whole mass was fibrous tissue (Fig. 2, *b*) arranged in concentric layers, and enclosing vessels (Fig. 2, *c*). No giant cells were visible in any of the sections examined. But the lesion was undoubtedly tuberculous in appearance. The semilunar ganglia and a portion of the left great spanchnic nerve were examined microscopically, but there was no evidence of any pathological change in these structures."



Manchester.

A SIMPLE APPARATUS FOR GASEOUS DISTENSION OF THE COLON:

WITH NOTES OF THREE CASES OF INTUSSUSCEPTION TREATED BY IT.

BY R. A. LUNDIE, M.A., B.SC., M.B., F.R.C.S. EDIN.,
ASSISTANT MEDICAL OFFICER, LONGMORE HOSPITAL, EDINBURGH.

IN a case of intussusception that came under my care some years ago I tried, among other methods of treatment, the introduction of the contents of a syphon bottle of soda-water through a rectal tube, as recommended by Treves[1] and others. While it did produce a rapid distension of the colon, this was obviously much less rapid than would have been the case had gas alone been used, and when the bowel contracted and expelled the mixture of water and gas it returned not without discomfort and inconvenience. The latter disadvantage is also present in the method strongly recommended by Von Ziemssen[2]—viz., introducing in succession into the rectum solutions of bicarbonate of soda and of tartaric acid. In the house where my next case occurred there happened to be a seltzogene, and it struck me that this could be made to answer my purpose better than an ordinary syphon. I found, as I expected, that it was a great improvement, and showed the device to the Edinburgh Medico-Chirurgical Society.[3] As I recently had the opportunity of using it in another case I think it well to make it more generally known.

The illustration renders description almost superfluous. It will be seen that the upper globe only is charged; I have found the most convenient method of effecting this to use the tartaric acid in large crystals, not in powder, in order that its solution and the consequent evolution of carbonic acid may be somewhat delayed. Pour as usual the charge, first of tartaric acid and then of bicarbonate of soda, into the

Hosted by Google

upper globe of the seltzogene; after adding a little water quickly withdraw the funnel, introduce the tube, and screw it home as speedily as possible. A piece of plain india-rubber tubing, with a rectal nozzle attached, completes the apparatus.

The patient's lower bowel should be emptied by an ordinary enema before distension with gas is tried. If this has been done it will be found possible to distend the colon several times in succession, allowing it time to expel the gas before more is introduced, without disturbance from escape of fluid. I have not found it necessary to press the buttocks together round the tube, or to resort to other means of preventing the escape of the gas, and so of increasing or prolonging the pressure and the distension of the colon. This could easily be done when desirable—e.g., if the method were employed for diagnostic purposes. Nor have I found it necessary to give chloroform; when pain is produced, though it may be sharp, it is only momentary. When the tap is opened it will be found that the gas escapes and the patient's abdomen distends very rapidly; a second or two will probably suffice to inflate the colon as much as is required. In this rapidity, it seems to me, lies the chief advantage of the method in the treatment of intussusception; strong and even pressure is brought to bear so quickly that the constricting muscular fibres have probably not time to contract in response to this stimulus until it has reached its full strength. As a dislocated shoulder-joint may sometimes be reduced with ease if the patient be taken unawares, and reflex fixation of the muscles thus avoided, so I think this sudden distension of the intestine anticipates, and so to a large extent escapes, the impediment to reduction caused by that reflex fixation of the intussusception which any stimulation of it is sure to produce. The latter case, moreover, presents one great advantage over the former; for the latent period of the unstriped muscular tissue with which we have to do is much longer than that of voluntary muscle.

It may appear at first sight a violent and dangerous method of treatment; but it must be remembered that the intestines are supported by the abdominal wall, and that so long as there is no gangrene or deep ulceration rupture is hardly possible. Indeed, Von Ziemssen says that he has tried in vain to rupture by inflation outside the abdomen intestine taken from the cadaver while still warm. If, however, the symptoms have been so severe or of such duration as to suggest the possibility of gangrene, inflation should not be attempted unless the operator is prepared to proceed at once to laparotomy in case of rupture. Though my experience is confined to cases where I believe intussusception was present, I have no doubt that this method might safely and profitably be employed at an early stage in various other forms of obstruction. In Von Ziemssen's paper above referred to many conditions are enumerated in which distension of the colon with gas may be of use both for diagnosis and treatment; and in any of these I think the device above described would be found convenient. It has probably been employed before, but I have been able to find no mention of it, and hope this note may induce those who have the opportunity to give it a trial.

I append very condensed notes of all the three cases in which I have used the apparatus. If the symptoms and signs observed do not actually demonstrate the presence of intussusception in any of them, yet that appeared to be the most probable explanation of severe and alarming abdominal symptoms in each; and as in each inflation was followed by immediate and striking improvement, and seemed the turning point in a very anxious case, their interest is not entirely dependent on the accuracy of that diagnosis.

CASE 1.—A woman, aged sixty years, was subject to occasional diarrhœa. On Oct. 11th, 1891, she had sharp pain in the abdomen on awaking in the morning. There was much vomiting. A small hard lump was noticed in the region of the gall-bladder. Morphia was administered. On the 12th there was much pain and vomiting. There was a much larger lump, very tender, elongated, below and parallel to the margin of the liver. The colon was thrice inflated in the evening; she had sharp pain each time. The elongated tumour had gone, and the pain and the tenderness had very greatly diminished. On the 13th there was renewed pain, but less severe; it was not relieved by inflation. This proved to be due to fæcal impaction, which was removed by enemata of olive oil continued for some days. Subsequently the patient had several attacks of fæcal impaction in the same region, but without anything to suggest intussusception. She died in 1895 from malignant tumour in the right hypochondrium. The exact origin was not made out.

CASE 2.—A delicate woman, thirty-four years of age, was subject to occasional attacks of abdominal pain. On the evening of Oct. 31st, 1892, she experienced sudden violent pain in the abdomen more severe than ever before, but not distinctly localised. The patient was much collapsed. No tumour was made out. Morphia was administered hypodermically. On Nov. 1st the pain and vomiting were controlled only by morphia. In the evening inflation gave no relief. Some blood-stained mucus was passed. On Nov. 2nd the patient was much in the same condition. In the evening inflation was repeated. There was sudden, sharp, localised pain above the pubes, followed by great relief. No more morphia was required, and rapid recovery followed.

CASE 3.—A boy, aged eleven years, healthy, but not very robust, on July 11th, 1896, after unusual exertion, ate a large and hurried meal, and continued to rush about afterwards. At 6 P.M. he was seized with sudden pain on the right side of the abdomen. There was localised tenderness from the liver to the right iliac fossa. Repeated vomiting occurred, followed each time by temporary relief. The symptoms continued after the stomach and bowels were empty. The patient had broken, restless sleep. The pulse was quick and small. The colon was thrice inflated in quick succession on July 12th, at 2 A.M. There was sharp pain at the time. Great relief followed; the pulse improved and sleep was sound and quiet. Vomiting continued at longer intervals till noon, but without any other bad symptom. Recovery was rapid.

ST. GEORGE'S HOSPITAL.

A CASE OF ACUTE PULMONARY GANGRENE IN A HEALTHY YOUTH; PYOPNEUMOTHORAX WITH SEVERE SYMPTOMS; INCISION AND DRAINAGE; RECOVERY.

(Under the care of Dr. W. EWART and Mr. MARMADUKE SHEILD.)

IT is curious that so striking a condition as gangrene of the lung was practically unrecognised until it was described by Laennec[1] in 1823. It is usual to deny the existence of cases of primary gangrene, cases in which there is no preceding morbid condition; but undoubtedly cases do occur, as the following report shows, in which pulmonary gangrene suddenly appears in persons who are, so far as can be ascertained, perfectly healthy. V. Babés[2] maintains that careful inquiry will always elicit some source of infection, such as tonsillitis, and Volkmann has insisted on the etiological importance of minute portions of food penetrating into the respiratory passages. The occurrence of micro-organisms in the sputum of pulmonary gangrene was first noticed by Virchow[3] in 1846; he described sarcinæ, and the frequent presence of the same bodies was recognised by Fischer.[4] In 1866 Leyden and Jaffé described the leptothrix pulmonalis as constantly occurring in pulmonary gangrene,[5] and their results were confirmed by Kannenberg.[6] Recent researches agree in the importance of bacteria in the production of gangrene of the

Hosted by Google

lungs, without, however, according to the leptothrix the exclusive *rôle* which Leyden and Jaffé attributed to it. There is probably no specific organism. The following case is one of those in which the gangrene is very superficial, when, as was first pointed out by Corbin,[7] consecutive pleurisy, often accompanied by pneumothorax is very common. The satisfactory result of the case is probably greatly due to the early stage at which the pyopneumothorax was drained.

A young man, aged eighteen years, was admitted into St. George's Hospital on April 14th, under the care of Dr. Ewart, suffering from pain in the back and cough. He had always been in good health and had never suffered from a cough; when a child he had measles, but had never had influenza. He was a teetotaler. His family history was good, and no relative of his had had phthisis. In appearance he was delicate, tall, and rather thin. His nails were almond-shaped and striated. On April 8th, about ten o'clock in the morning, the patient had been attacked by a feeling of chilliness. This, though severe, hardly amounted to a rigor, as his teeth did not chatter, and there was but slight shivering. He was able to keep about, but on April 9th he had to take to his bed, as he was seized with severe pain in the left shoulder (supra-spinous region), passing downwards to below the inferior angle of the left scapula. On the 10th the pain and cough continued, but he did not expectorate; his weakness was so great that he was compelled to lie on his back, and he was unable to move. For the next four days the pain persisted and the cough also, but still there was no expectoration. He felt hot at times and sometimes shivered. On examination, after his admission on the 14th, he looked very ill and lay on his back in bed, and complained of his weakness and inability to move. His lips and ears were slightly but distinctly cyanosed. The pulse was 88 and the respirations were 36. His heart was apparently normal, no murmurs could be heard, and the apex beat was situated in the fifth space two and a half inches from the sternal margin. On auscultation numerous scattered râles could be heard over both sides of the chest in front. Behind, on the left side, there was dulness downwards from the inferior angle of the scapula, with weakening of the breath sounds, and vocal resonance was deficient over the same area. Scattered râles could be heard on both sides. Owing to pain and fixation of the chest he was unable to spit out the secretion which rose. His tongue was greatly furred. The urine was normal. His temperature was 101° F. A diagnosis of diffused broncho-pneumonia, probably post-influenzal in origin, was made. In the evening of this day the temperature rose to 102·4°; he had a fairly good night, but on the morning of the 15th it was noticed that his breath was very offensive when he coughed. The temperature was normal at 10 A.M., but in the evening it rose to 101·6°. On the 16th the cough continued to be very severe, and one fit of coughing culminated in his vomiting a large amount of whitish foul-smelling muco-pus. The pain continued to be severe. The evening temperature was 99°. On the 17th he felt much more comfortable; his cough was decidedly less, but he had brought up a small quantity of extremely offensive sputum. His face was less flushed. From the 18th to the 25th the symptoms and physical signs continued unchanged, except that dulness in the left upper scapular region became noticeable. He slept well, and his temperature, though very variable, hardly rose above 101°. During the night of the 25th he complained of severe pain in the lower part of the left side of the chest; this pain was relieved by morphia. On the 26th there was dulness on percussion over the left side of the chest as high as the angle of the scapula, with bronchial breathing and bronchophony and decrease of the vocal fremitus—in short, all the signs of empyema. On the 27th preparations were made for aspiration, but finding on re-examination that hyper-resonance had replaced the dulness at the left scapular region Dr. Ewart decided not to aspirate. The occurrence of a limited pneumothorax was suspected, but as a careful examination showed that the heart was not displaced to the right an alternative diagnosis was made of bronchiectasis with sudden evacuation of the contents of the cavity. On the 28th the patient's cough was still very troublesome. He had orthopnœa; the cyanosis was more marked, the pulse very rapid, and the exhaustion extreme. The temperature was 102°. The apex beat was now distinctly displaced to the right, and could be felt in the fifth space one inch to the left of the sternum. Over the upper half of the left side of the chest, both front and back, there were hyper-resonance and loss of breath-sounds, but the lower part continued to be dull. The breath was very offensive, and there was urgent difficulty of breathing. Full confirmation having now been obtained for the diagnosis of gangrene of the lung rupturing into the left pleural cavity and giving rise to pyopneumothorax, Mr. Marmaduke Sheild was called in with a view to operation. Chloroform having been administered, an incision was made into the left pleural cavity through the sixth intercostal space immediately behind the mid-axillary line. A large amount of very fœtid pus and gas escaped and an empyema tube was inserted. At the end of the operation it was found that the heart's apex beat had returned to its normal position. On the 29th, after a fair night, with very little cough and little expectoration, the patient's breathing was still rapid, but his general condition had much improved. On dressing the wound a large quantity of very fœtid pus came away. The amount of discharge steadily diminished, the fœtor became less marked, and he rapidly improved in health. On June 11th the wound, though not yet healed, was small, and from it came but a small quantity of pus, which had no unpleasant odour. Breath-sounds could be heard close up to the margin of the wound in front and above, and also posteriorly down to the level of the incision; but behind and below the breath-sounds were not audible, and this area was dull on percussion. The left side of the chest had noticeably fallen in.

Remarks by Dr. EWART.—The points of interest in this case were the patient's early age, healthy antecedents and surroundings, and the absence of any clue as to the source of infection or of septic influence; the changes in the physical signs, which led to the case being viewed in succession as one of broncho-pneumonia, of empyema, of bronchiectasis, and of gangrene with pneumothorax; the almost desperate condition of the patient at the time of the operation; and, finally, the complete recovery, thanks to the latter.

Medical Societies.

KIDDERMINSTER MEDICAL SOCIETY.

Punctured Wound of Abdomen.—Exhibition of Cases and Specimens.

A MEETING of this society was held at the Kidderminster Infirmary on May 28th, Mr. S. STRETTON being in the chair.

Dr. THOMPSON sent notes of a case of Punctured Wound of the Abdomen with Prolapse of about eight inches of Bowel. The patient was a girl, aged four years, who was brought from the country four miles in a spring cart with the protruded bowel covered by a wet cloth. Chloroform was administered, the opening was enlarged, the wound was stitched up, and a pad and bandage were applied. The child was then driven home in heavy rain. She had no bad symptoms and made an uneventful recovery.

Mr. J. L. STRETTON showed a patient upon whom he had performed Cholecystenterostomy. The first part of the operation was performed, and the Murphy's button was passed on the fourteenth day. There was a considerable discharge of bile and fæces through the gall-bladder, to allay which it was plugged with iodoform gauze, when the discharge appeared to cease. The second operation was then performed. An elliptical incision, including the fistulous opening, was made; the edges of the opening were then freshened, and it was closed with deep sutures, the elliptical opening being brought together over it. The wound healed without any trouble, and the fæces now contained bile, which they had not done prior to operation, showing that there was some communication between the gall-bladder and intestine. Although in this case the operation had been divided, Mr. Stretton thought it would be better in future cases to perform it at one time for fear of the contraction of the newly formed opening.—Mr. STRETTON also showed Seven Calculi weighing sixty grains in the dry state removed from the urethra of a youth. Six of them were in the fossa navicularis faceted together, and were removed with urethral forceps.

Hosted by Google

Some few months later the seventh was found impacted in the bulbous urethra and was cut down upon.

Mr. J. P. HOLYOAKE and Mr. E. H. ADDENBROOKE also described cases of Urethral Calculi.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Treatment of Puerperal Septicæmia.—Exhibition of Specimens.

A MEETING of this society was held in the board room of the Medical School, Leeds, on May 27th, Mr. H. BRIGGS, President, being in the chair.

Dr. BRAITHWAITE (Leeds) contributed a paper on the Treatment of Puerperal Septicæmia, based upon sixty-three cases seen in the last eight years. In four cases he had used anti-streptococcic serum, and in three out of the four a considerable reduction of temperature followed, but it was uncertain how much of this was due to douching, purgatives, and other treatment. The serum should be employed at the onset of the fever.—A discussion followed, in which the PRESIDENT, Professor C. J. WRIGHT, Mr. CROFT, Mr. RICHARDSON, Dr. HELLIER, and Dr. GEMMELL took part.

Professor C. J. WRIGHT (Leeds) showed the following specimens: (1) Some Molar Masses removed from a Uterus four weeks after the birth of a living child; there had probably been a twin conception with one ovum blighted; the masses consisted of granulation tissue and contained a few bits of placental structure; and (2) the Placenta from a case of Triplets; this was one large placenta with two cords and a smaller one with one œdematous funis; the amniotic sacs were separate.

Mr. W. A. STOTT (Leeds) showed specimens of Carcinomatous Ovaries, Double Hydrosalpinx, and Double Pyosalpinx.

Mr. CROFT (Leeds) showed a Ruptured Female Bladder. The patient had been operated upon for hæmorrhoids; there was no subsequent retention of urine or catheterisation. On the eighth day there were abdominal pain and distension, followed by a diminution in the quantity of urine passed and symptoms of uræmia. The patient died from uræmia, and post mortem there was no evidence of peritonitis, adhesions, tubercle, or abscess in the pelvis or abdomen.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Recent Failure of Hospital Accommodation in Dublin.

A MEETING of this section was held on May 10th, Dr. J. M. REDMOND, President, being in the chair.

Sir CHARLES CAMERON read a paper on the Recent Failure of Hospital Accommodation in Dublin. He mentioned that in 1895 he proposed the institution of a hospitals board for Dublin city and county on the lines of the London Asylums Board, and the scheme was approved of by several of the local authorities, particularly by the North Dublin Board of Guardians, but it was opposed by the council of the Dublin Sanitary Association and by the physicians of several of the Dublin hospitals. Three arguments were used against it: (1) that it would be enormously costly; (2) that there was ample accommodation for the treatment of infectious diseases in existing hospitals; and (3) that it would interfere with medical education. Sir Charles Cameron, however, argued that the existing hospital accommodation was last year proved to be quite insufficient, and that the scheme would, as alleged, seriously interfere with medical education seems improbable, for no one can deny that Edinburgh and Glasgow are medical schools of the first rank, and yet the students in those cities have to go to special fever hospitals to acquire a knowledge of contagious diseases. It is the same in London and other places. Last year when measles became epidemic in Dublin scarlet fever also was prevalent, and the severer cases of those diseases were so numerous that the hospitals were crowded with them. Very bad cases of measles and erysipelas had to be retained in tenements of the most wretched kind, as no hospital accommodation could be procured for them. At the period when the congestion of the hospitals had attained its maximum small-pox broke out on the south side of the city, and no hospital was in a position to admit the first three patients, but fortunately the disease did not spread. In any future epidemic of small-pox it would be desirable to have hospital accommodation outside the city. As regards measles there will always be a difficulty in providing accommodation for its victims on account of the great number of patients. In Glasgow a determination has recently been arrived at to provide full accommodation to meet the wants of the largest epidemic of this disease, and in Edinburgh the foundation-stone of a fever hospital has just been laid which will accommodate 600 patients, including measles cases. Sir Charles Cameron was, on the above grounds, still of opinion that an infectious diseases hospitals board should be constituted for the Dublin district, and that the board should establish a small hospital, a home for convalescents, and make provision for epidemics of measles or scarlet fever.

Dr. FALKINER said that the hospital accommodation in Dublin was quite insufficient in the event of three or four epidemics occurring at the same time. He considered that measles was not a disease which must spread broadcast of necessity.

Dr. J. W. MOORE strongly advocated an isolation hospital for small-pox, and thought it a disgrace that Dublin did not possess such a hospital.

Reviews and Notices of Books.

Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners. By H. MACNAUGHTON-JONES, M.D., M.Ch., M.A.O. (*Honoris Causâ*) R.U.I., &c. Seventh Edition. Revised and enlarged, with 565 Illustrations. London: Baillière, Tindall, and Cox. 1897. Price 15*s*.

WE are told in the preface "that no previous issue of this work has undergone such complete revision and re-construction as the present one, both in the re-arrangement of the order in which the subject is dealt with, the numerous additions which have been made to the text, and in the large number of illustrations it contains." We observe that attention is called to a recent trial which "has shown how careful the operator and those assisting him should be to make no observation on the case while the patient is in the condition of semi-anæsthesia." The author has not apparently shaken himself entirely free from the teachings of the mechanical system of uterine pathology, so much in fashion twenty years or more ago, as version and flexion are retained on his list as causes of dysmenorrhœa, and a large number of pessaries, including intra-uterine stem pessaries, are still figured. Dr. Macnaughton-Jones advocates forcible dilatation of the sphincters under ether in obstinate constipation. He relates the following case:—

"A lady from —— consulted me for constipation ..... she had ever since [her confinement] been relieved by enemata and with difficulty. ..... On examination I found the uterus healthy and in its normal position, the rectum loaded and hæmorrhoidal. There was a vaginal leucorrhœa. The following day, under ether, I forcibly, with my hand, dilated the sphincters. A few fibres of the external were ruptured; the rectum was emptied of its contents. An olive oil enema was given the next morning. She was placed on cascara sagrada and a mild pill of belladonna and nux vomica, and from this to the day she left England, a period of four months, the bowel was regular, and she never used an enema."

It is not very easy to see what harm there would have been in trying the effect of the olive oil enema followed by cascara and the mild pill before stretching this patient's sphincters forcibly with the hand, especially as she was not leaving England till four months later, but no doubt the author had his own reasons for the course adopted.

We do not think the author describes Hegar's sign of pregnancy quite correctly. He says it consists in the

Hosted by Google

uterus losing its pear-shaped outline; "the body is bellied out over the cervix in all the transverse diameters, especially antero-posteriorly." This does not seem to be quite clear. Hegar's sign consists in the very marked softening that takes place during early pregnancy in the uterus at the level of the internal os. This softening is so marked in some cases that on bimanual examination the enlarged body of the uterus has at times actually been mistaken for a tumour separate from the uterus. We observe, by the way, that several proper names are spelt somewhat erratically, which we should not have expected in a seventh edition. Thus Dr. Herman appears several times as Dr. Hermann; Mr. Targett is particularly unfortunate, appearing as Dr. Taggert in the index and at p. 558, and as Mr. Torgert at p. 786; Budin appears twice as Buden; even Spiegelberg is given twice as Spiedelberg; and Paquelin given once at least as Pacquelin. Dr. Macnaughton-Jones still thinks that Sir John Williams's views on cancer of the cervix are not borne out "either by clinical experience or the pathological researches of others." We have rarely seen a book in which the quotations from the writings of other authors are so long and so numerous as in the one before us. As the author states that the book is intended for the student as well as for the practitioner we think it right to say that to our thinking the student knowing nothing of the subject wants something more dogmatic. Thus, at one place the author says he agrees in the main with the opinion expressed by Matthews Duncan in his lecture on "Minor Displacements," and yet he approves of dividing the cervix in some cases of anteflexion and figures a long array of pessaries, including eighteen or twenty figures of intra-uterine stems.

In the chapter on Uterine Displacements there is a long list of some results, direct and indirect, of uterine versions and flexions. Among the results are amenorrhœa, menorrhagia, and metrorrhagia, uterine fibroids, perimetritis, and pelvic phlegmon. The author in the preface claims that his book is an epitome of the teaching and opinions of the greatest living gynæcologists. We think the author is here mistaken to some extent; we do not believe there is a teacher of gynæcology at any one of the London medical schools who believes that, for instance, pelvic phlegmon, perimetritis and uterine fibroids are caused, directly or indirectly, by uterine versions or flexions. We are glad to see that total extirpation of the uterus for prolapse is not countenanced by the author. Although the danger in capable hands may not be great, yet we agree with the opinion he quotes, that "the danger of a surgical proceeding should be at least not greater than the danger to life of the condition which the operation is destined to cure." Among the more noticeable features of the book are the abstracts of the various methods of operating on uterine fibroids. Thus there are good descriptions of Doyen's panhysterectomy, and of Baer's operation among the operations that dispense with the clamp, and of Taylor's method of clamping the pedicle when the extra-peritoneal method is employed. Martin's description of his method of operating is also quoted, and is accompanied by his excellent illustrations, which originally appeared in the Transactions of the Obstetrical Society of Edinburgh. The process by which they have been reproduced has not brought them out quite so sharp as the original figures, but they are clear enough to follow. The chapter on tubal pregnancy, short but remarkably clear, has been revised by Mr. Bland Sutton, and is in every way excellent. There is an extremely large number of formulæ for lotions, medicines, and applications scattered through the book, which will probably form an attractive feature, and there is also a large number of suggestions on the important matter of treatment. There is, too, a useful list of the principal foreign and home spas, with a note of the chief characters of the waters at each.

There is now such a large number of operations, major and minor, in gynæcological practice that it is convenient to have descriptions of them under one cover for reference. We think that there are very few of these operations to which some reference will not be found in the book before us.

DR. RENTOUL'S MIDWIFERY NURSES' REGISTRATION BILL.

DR. R. R. RENTOUL deserves commendation for his unwearied efforts to arrive at a satisfactory solution of the midwives question, but he has not arrived there yet.

The subject is one in which the medical profession is interested in a variety of ways, and the opinions of representative medical men will no doubt influence the action of politicians in shaping the legislative measures which have become inevitable. Dr. Rentoul's draft Bill is entitled, "An Act to Provide for the Training, Compulsory Registration, and Supervision of Midwifery Nurses." The object of the Bill, which is to be applicable to the United Kingdom of Great Britain and Ireland, is to protect the general public, and especially its more uneducated members, so that they may know who are trained midwifery nurses. The Bill does not make it illegal for any woman to help another in a friendly manner, neither does it interfere in any way with existing midwives, but it would put a stop to the holding of examinations and the granting of documents which profess to entitle women to call themselves midwives and to act as such. The leading features of the draft Bill are—(1) the special appropriation of the term "midwifery nurse," with heavy penalties for infringement; and (2) the creation of a "divisional midwifery nurses' board" in each of the three divisions of the United Kingdom. The "midwifery nurse" is defined as "a woman who acts, or is entitled to act, as a midwifery nurse in *all* cases of labour under the direct supervision of a registered medical practitioner, and who nurses mothers and infants under such regulations as are laid down in this Act, or which shall be from time to time laid down by the divisional midwifery nurses' boards." The principal rights and privileges conferred on her, as well as the disabilities and penalties to which she may become liable are as follows: "No person, except such as are registered under this Act, shall be entitled to take or use the name or designation of midwifery nurse, either alone or in combination with any other word or words or letters, or any name, designation, word, addition, or description implying that such person is registered under this Act," the penalty for infringement hereof being liability to "a fine not exceeding £10 for the first offence and £20 for the second or subsequent offence, and to imprisonment until such fine be paid."..... "No person unless registered under this Act shall act as a midwifery nurse in any hospital, infirmary, dispensary ..... or under the supervision or control of any registered medical practitioner." ..... "No person shall be entitled to privately ask for or receive or recover any wages or charge in any court of law for services rendered as a midwifery nurse unless such person is registered under this Act." ..... A certificate of registration under this Act does not render its holder "entitled to grant any certificate of the fact or cause of death, or a certificate of the cause or fact of stillbirth, or any medical certificate. Any person contravening the terms of this Section shall be liable to a fine not exceeding £20 and all costs of suit." ..... "No person shall be granted a certificate of registration to act as a nurse whose age is under twenty-five or over sixty years." ..... "A certificate of training in the duties of a nurse shall not be accepted by the divisional board or committee of examiners unless such lectures or training have been given by a registered medical practitioner." ..... "The period of training ..... shall not be less than six months or more than twelve months." ..... "If any nurse shall conduct any confinement upon her sole responsibility, or shall keep in her possession or use any midwifery forceps, sound, perforator, or any other appliance or instrument or drug, or shall upon her sole responsibility administer any drug to any woman or infant she shall be liable to be censured or suspended or fined or have her name removed by the board from the register." ..... "If any

Hosted by Google

nurse shall keep any shop or place for the supply or sale of drugs of any kind her name ..... shall be removed from the register."

Dr. Rentoul proposes to establish in each of the three divisions of the United Kingdom a "Divisional Midwifery Nurses' Board," for the purpose of appointing committees of examiners, keeping registers, &c., the board in England and Wales to consist of eleven medical practitioners, and those in Scotland and Ireland of eight each. The divisional boards are to be elected every fifth year, one member being chosen by each of the six Royal Colleges, one by each of the three Local Government Boards, three members in England and Wales, and one each in Scotland and Ireland by the medical staffs of voluntary lying-in hospitals specified in an annexed schedule, five in England and Wales, and four each in Scotland and Ireland by the registered medical practitioners engaged in practice. "Each divisional board shall be constituted and shall hold its first meeting ..... in such time and place as the President of the General Medical Council shall appoint, and shall draw up regulations as to the time and place of the meetings of the divisional boards and such other regulations as are provided for in this Act, and shall submit such regulations for approval or otherwise to the General Medical Council and to the Privy Council." ..... "The regulations for the guidance of boards shall be drawn up by the divisional boards ..... and may from time to time be revoked, altered, or amended. The same uniform regulations shall apply to each and all of the boards. The regulations so drawn up or amended shall be forwarded to the General Medical Council and to the Privy Council to be approved of or otherwise. ..... The regulations shall be framed in such manner as to secure in each part of the United Kingdom one uniform standard as regards the period of training, the subjects of training, age of entry for examination, conduct of examinations, conduct of registered midwifery nurses, and of all such subjects coming under the notice and authority of each divisional board. Provided that the course of instruction and of examination of candidates for the certificate of registration as midwifery nurse shall not include the theory or practice of medicine, or of surgery, or of midwifery, or of pharmacy, or of dentistry, or any part or branch of these subjects. Provided, also, that if any nurse shall obtain any authority to practise pharmacy or dentistry, or any branch of medicine, surgery, or midwifery, she shall cease to have her name registered on the midwifery nurses register and to act as a midwifery nurse." ..... The board for England and Wales shall each year appoint three committees of examiners, who must be registered medical practitioners, to hold examinations in three different parts of England and Wales; the boards for Scotland and for Ireland shall in like manner appoint two similar committees to examine in two different parts of their respective countries. Each committee shall consist of two persons exclusive of the chairman, and shall meet as often as may be directed by its board. "There shall be paid to the divisional board by each woman who presents herself for examination a fee of £1, half this sum to be charged if she fails in one examination and presents herself for a subsequent examination. The original registration fee for each person registered shall be £1, inclusive of the annual registration fee." ..... "From and after the date of the passing of this Act no person or persons or company or body of persons, or any authority or body now holding any examination or granting any document ..... shall hold any examination or grant any certificate or document which professes to empower any person to act as a midwifery nurse, except as provided in this Act, under a penalty for each such offence of not less than £100, and no person or persons shall ..... hold any examination or grant any document which professes to entitle any person to act as a midwife under a penalty for each such offence of £50, any Act of Parliament or charter or regulation to the contrary notwithstanding. Nothing in this Act contained shall ..... in any way affect the occupation of any woman who at the time of the passing of this Act acts or possesses a certificate which professes to entitle such woman to act as a midwife." ..... "The secretary of each examining committee shall ..... transmit a list of the names of the successful candidates to the divisional board ..... and the registrar ..... shall on receiving the registration fee from the nurse forward to her at her address a certificate of registration." ..... "Every nurse shall each year ..... obtain from the divisional registrar ..... a certificate of registration," the fee for which annual certificate shall be 3*s*. 6*d*. "A midwifery nurse shall within one month of her settling in a district to act as nurse, and in every succeeding year, take or send her certificate of registration to the clerk of the local sanitary authority of the district in which she purposes to act as nurse. The clerk shall keep a written alphabetically-arranged list of the names of such nurses, with their addresses. ..... No fee shall be charged to such nurse for showing her certificate of registration to the clerk. The list of the names and addresses of such nurses shall be open for the inspection of any person during the hours at which the office of the clerk is open, and no fee shall be charged for such inspection. Certified copies of such list of nurses shall be forwarded each year by the clerk of each local sanitary authority in the United Kingdom to the divisional board of that division of the kingdom in which the sanitary authority is situated."

The above extracts, which are not given exactly in the order in which they appear in the draft Bill, sufficiently indicate its essential features. It fills nine printed foolscap pages, not including the Memorandum, the Arrangement of Clauses, and the Schedules. There are various clauses relative to offences of sundry kinds, and among them it is provided that if any registered medical practitioner shall wilfully or knowingly employ any registered midwifery nurse to perform any duties other than those laid down or provided for in this Act complaint may be made to the General Medical Council, which may strike him off the Medical Register for two years. The proposal most difficult of comprehension is Clause 9 (1) (*g*) already quoted, which provides "that the course of instruction and of examination of candidates for the certificate of registration as midwifery nurse shall not include the theory or practice of medicine or of surgery or of midwifery." No provision seems to be made for midwifery practice apart from, or in the absence of, a medical practitioner, neither is there any indication of the means which it is proposed to adopt for the discovery and prosecution of offenders. Prosecutions by medical men, whether as individuals or associations, would obviously be unadvisable from every point of view. It is probable that the quinquennial elections of direct representatives to the divisional boards would excite anything but enthusiasm among the electors; but whatever modifications in details may be subsequently introduced, there is no denying the soundness of the general principle that this important branch of medical practice ought to be retained under adequate medical supervision.

THE SOCIETY OF CHARTERED NURSES. — Her Royal Highness the Princess Christian has graciously consented to become the President of the Society of Chartered Nurses, 24, Princes-street, Cavendish-square, W. This society was founded to supply to the public thoroughly competent private nurses. It is under the management of a professional committee, and being conducted on coöperative principles secures to each nurse the full remuneration of her work.

PRESENTATIONS TO MEDICAL MEN.—Mr. H. M. Page, M.D. Brux., M.R.C.S. Eng., D.P.H. Camb., of Redditch, has been presented with a silk umbrella by the Midland Railway Company's Redditch Ambulance Class in recognition of services rendered as lecturer; he has also received a dressing-case from members of the police force.—Mr. James Atkinson, L.R.C.P. Edin., M.R.C.S. Eng., of Crewe, has been presented with an instrument bag by the railway workmen on the Crewe works as an acknowledgment of instruction given to the local ambulance class.—Mr. S. Andrews, L.R.C.P. Lond., M.R.C.S. Eng., of Basingstoke, has received from the local ambulance class a silver-mounted surgical case (containing a hypodermic syringe, &c.), with inscription.—Mr. Geo. H. Johnson, L.R.C.P. Edin., M.R.C.S., of Teignmouth, has been presented with a pocket barometer by the local ambulance class in recognition of services rendered as instructor.—On May 28th the members of the Pride of Cornwall Lodge of Oddfellows presented Mr. Charles W. Chubb, M.R.C.S. Eng., L.S.A., of Torpoint, Cornwall, with a handsome silver tea urn, inscribed as follows: "Presented to C. W. Chubb, Esq., as a token of respect and esteem from the members of the Pride of Cornwall Lodge, M.U. I.O.O.F., Torpoint, on his resignation after fifty-one years' connexion as surgeon." The juvenile members of the society gave Mr. Chubb a claret-jug and a walking-stick.

Dicant triumphi pacis et ingeni
Humanioris, partaque civibus
Cum lege libertas, et alma
Religio genetrix Salutis:

Dicant et artes muneraque indolis
Carae Camenis, seu lapidi datur
Vis viva, seu pictis tabellis
Eloquium, geniusve libris:

Dicant paternae provida Curiae
Consulta, et imis aequa reis Fora, et
Ordo Sacerdotum verendus
Rite gerens Cruce se minorem.

Testes tot inter nec comitem abneget
Mens Æsculapi, militis unice
Pugnacis et nacti tropaea
Non ducibus data bellicosis;

Quo civitatem quis status adjuvet
Curante, pestes inque aciem cohors
Producta causarum facessunt,
Terga vel ante tubas daturae;

Qui sopit aegros rore per halitum
Donante lethen, ne metuant pati
Ferrum quod admorit severum
Vimque salutiferam Machaon;

Qui cultor audens nec tamen impius
Rerum parentis scit penetralia
Intrare vitae non profanis
Luminibus prius haurienda,

Morbumque in antris opprimere intimis,
Ut dormientem Protea, mox sua
Consilia aperturum, quot arma
Ludere, quot soleat timere,

Mos unde nobis normaque sanior
Deducta firment et genus et domos
Dum major integremur aetas
Inque vetus referamur aurum.

Princeps ter alma et tot sata regibus
VICTORIA! Orbi praebita, ceu redux
Astraea, et adscribenda caelo,—
Sera tuis abeas alumnis!

Praesentiori numine nam tuo
Fortuna nobis defluet amplior
Illi propinquatura metae
Usque pils animis petitae,

Quo cum mearint, verius Insulas
Visent Beatas quam vagus Hercules,
Audax Atlanteas per undas
Hespecidum rapuisse poma.

J. P. STEELE,
M.D. EDIN.

Badae Helvetiorum
Id. Jun. MDCCCXCVII.

ARGUMENT.—The Muse of History, invoked to reveal the origin of Britain's greatness, recounts the Claudian subjugation of the Silures and the prophetic discourse of their chief, Caractacus, before the Emperor's tribunal. In four centuries from that date Rome will succumb to the Barbarian North, for (adds Caractacus) Ulysses in his last voyage in quest of the Happy Isles, being storm-stayed on the British coast, was hospitably entertained, and, in return, predicted the future power and expansion of his hosts till, under a "QUEEN and EMPRESS," they would rule a world wider than that of Rome, purer in religion, and more civilised. How far that prophecy, recalled from the grey foretime by Caractacus, has been fulfilled let the contemporary world attest by the triumphs of peace, of liberty under law, and of Christianity; by the fine arts—sculpture, painting, literature; by the Senate, the courts of Equity, and the Church; but not least by the triumphs of the Healing Art, as seen in State Hygiene, in painless Obstetrics and Surgery, in the treasure-trove of Physiology and Pathology, giving the key to the inmost recesses of the human organism, surprising latent Disease like the sleeping Proteus, and forcing it to give up its secrets as to the cause, the course, and the cure of suffering. To the advance of Medicine there is no bound, accelerated as it is by the enlightened sway of the QUEEN and EMPRESS in the character of "Astraea Redux." May that blessed sway continue! The true "Islands of the Blest." J. P. S.

THE LANCET.

LONDON: SATURDAY, JUNE 19, 1897.

1837. MEDICINE AND THE MEDICAL MAN. 1897.

To tell the story of the progress of medicine during HER MAJESTY'S splendid reign—a reign not only unprecedented in length but in scientific discovery and development of all sorts—would be manifestly impossible within the scope of the editorial statement of a weekly journal. Space will not allow us to enter into detail when a period of sixty years, no year of which has been barren of result, has to be covered. A mere list of the names of men whose life-work has added to the stores of our special knowledge could with difficulty be compressed into the scope of this article if the list were to be exhaustive and to include all whose work directly or indirectly has conduced to the advance of scientific medicine. For as medicine has been metamorphosed from an art into a science the taxes which she levies upon the sister sciences have grown heavier and heavier, until the present position is reached, where the surgeon's aptest assistant is applied chemico-physiological procedure of the most elaborate sort, and where the physician displays the single-heartedness of his studies by employing in his therapeutics an accurate knowledge of electrical phenomena. In the brief account of medical progress during the past sixty years which now follows we have attempted to call attention to the most important steps forward. And we are justly proud of being able to say that if anyone should desire to know more of particular circumstances in this grand record of advance he can consult our columns in the past. For THE LANCET was born fourteen years before HER GRACIOUS MAJESTY ascended the throne, and within its covers will be found the true and exhaustive history of medical progress during the reign.

We start our summary with a brief *résumé* of the advances in our knowledge of physiology and chemistry, for to the enormous strides that these sciences have taken we must attribute much of the success that attends medical practice of the present day. In diagnosis, in prophylaxis, and in therapy alike our methods are now based upon scientific research. But let no one look with anything but respect on the great men of the past whose labours were effected under a less favourable environment. In the "thirties" and "forties" there were giants in the land, and the work that they did has been of incalculable value. Advances in the ancillary sciences could not have been grafted with success upon an empirical scheme. It is because the old work was good and honest and thorough—it is because when true reasons for procedure were absent false reasons were never invented—that medical routine was in a healthy condition and ready to take advantage of all tribute brought to it from exoteric sources. We are sure that no one can read the names of the heroes of medicine in the early Victorian days without feeling that a debt of gratitude and reverence is owing to them, for their technical knowledge, for their intuition, and for their honourable methods.

THE GROWTH OF PHYSIOLOGICAL AND BIOLOGICAL KNOWLEDGE.

To give even a short account of the advances that have been made in physiology and in physiological chemistry during the past sixty years would require a volume. The doctrine of the correlation of forces and the doctrine of evolution have profoundly modified our conceptions of the nature of life and of the secondary causes which have led to origin and diversity of the forms of life by which we are surrounded. We can hardly place ourselves in the position occupied by workers before DARWIN'S revelations and HUXLEY'S magnificent support of them. For the relations of HUXLEY to DARWIN—with LISTER and PASTEUR the foremost scientific names of the Victorian era—are deeply interesting. Without HUXLEY'S powerful aid, valuable corroborative evidence, and telling exposition of the doctrines of evolution DARWIN'S views would certainly have been far more slowly accepted.

PROFESSOR HUXLEY.

The importance of the cell as the physiological unit common to all the tissues of the body has been fully established, though the estimation of the relative value of its component parts—cell-wall, protoplasm, and nucleus—has of late years undergone material modification, whilst each has been shown to possess a structure far more complex than was believed to exist by the originators of the cell theory, SCHLEIDEN and SCHWANN, or even by VIRCHOW, who twenty years later so ably supported the doctrine of "omnis cellula e cellulâ." The successive improvements made in the construction of the microscope have proved of immense service to physiology by enabling observers to comprehend the structure of the different organs of the body, and thus to gain some insight into the mechanism by which the various functions of secretion, sensation, and motion are effected. We are still only on the threshold of this inquiry and are

Hosted by Google

very far from comprehending the mode in which this mechanism acts; but the little knowledge that has been gained has served to sweep away much that was inaccurate and even absurd in the opinions and practice of our immediate predecessors, and to establish better, because more rational, methods of treatment of disease.

Experimental physiology dates back to the time of GALEN, and a few names, like those of HARVEY and HALES, stand out in strong relief as experimentalists in the period of revival from the long sleep of science during the Middle Ages; but at no time has it been pursued so energetically as in the last few decades, or with more instructive and satisfactory results. In France the mantle of a great experimentalist, MAGENDIE, fell on the shoulders of a still more successful investigator, CLAUDE BERNARD, to whom physiology is indebted for some of the most striking discoveries of this period. His lectures delivered before the Collège de France or read before the Académie des Sciences were a succession of surprises. Now it was the effects upon the several constituents of food of the different fluids poured into the alimentary canal, the salivary, gastric, biliary, pancreatic, and intestinal juices; now it was a novel function of the liver in the production of sugar; now the action of the sympathetic system on the production of heat, or the effects of various toxic agents as curara and strychnia on nerve and muscle. Subsequent research and the keen criticism of acute observers in other countries have modified some of his results, but the originality and ingenuity of his experiments command admiration, and he must always be regarded as one of the foremost men of his time. The mode of teaching adopted by LUDWIG in Vienna also gave a great impulse to the study of experimental physiology, for he not only did much original work, but he founded a school; in many instances he suggested the subject to be investigated to his pupils, pointed out the mode in which it should be attacked, supplied all necessary apparatus, assisted the student when requisite with his practised eye and hand, and whilst leaving him to take the notes finally put the whole into due order; then with infinite good nature he allowed the young experimenter to publish the results in his own name, so that the initiated alone knew how much was due to the master, thus creating a debt of gratitude which none of his pupils thought could be overpaid. Following the same lines MICHAEL FOSTER established a school of young physiologists at Cambridge, and the work they have accomplished, as recorded in the *Journal of Physiology*, will bear comparison with any of the great continental schools.

It is of small importance what section of physiology is selected to illustrate the immense advances that have been made by the combined labours of numerous painstaking and accurate observers in many different countries. The blood has not been the subject of more research than nerve or glandular structures, yet it is easy to show that our knowledge has been rendered far more exact of late years in regard to the form, size, and number of the corpuscles; of the relative proportions of the coloured and uncoloured, of the spontaneous movements of the latter, and of their ability traverse the walls of the vessels; of the origin of the coloured corpuscles and the effects of reagents upon them, of their chemical composition, and of the nature, quality, and exchange of gases during their passage through the capillaries of the lungs and those of the tissues; while such points as the crystallisation of the hæmoglobin and the phenomena of spectrum analysis are altogether of recent date. More striking still are the accessions to our former knowledge of the phenomena that can be demonstrated in the nervo-muscular apparatus. The form and speed of the ave of contraction in muscle, the rapidity with which the impulses causing sensation and motion are propagated in nerve, the functions of the several columns of the spinal cord, the long denied reaction of the brain cortex to stimulation, have been rendered probable or actually demonstrated by the converging and mutually supporting lines of careful dissection, microscopic examination, experimental and pathological inquiry, and embryological research, whilst comparative anatomy has now and again afforded additional evidence when proof from other sources was wanting.

Of late years the physiological chemist has been persistently engaged in the investigation of the changes undergone by the proximate principles of food—as starch, sugar, fat, and proteids—not only in the alimentary canal, where the first steps in their assimilation are accomplished, but in their passage through the economy, until they are discharged either partially oxidised in the form of urea, lactic, uric, and hippuric acids, creatinin, and the like, or completely burnt in the form of water and carbon dioxide. Great progress has been made in the discovery of the primary changes that occur, such as the origin of sugar from amyloid substances, the emulsification and saponification of fats, the production of peptones from proteids with the subsequent formation of leucin and tyrosin, the aromatic compounds (indol, phenol, and skatol), and others, but many of the more recondite changes in the blood and in the tissues still await explanation. There is every reason to anticipate that such explanations will be forthcoming, and that in process of time we shall know all the intermediate changes. In several Continental universities, departments or laboratories have been instituted where physiological chemistry can be taught and pursued, and where problems hitherto regarded as insoluble are persistently attacked with good hope of success.

The physiological researches of PASTEUR, applied to medicine and surgery by LISTER, have borne magnificent fruit, more particular reference to which will properly follow.

CHEMISTRY IN RELATION TO THERAPEUTICS.

To record the progress of chemistry during the last six decades would be equivalent to writing a complete history of its evolution. Chemistry, in short, was born in the Victorian era, and grew with a pace second to no other branch of inquiry. This enormous progress has had a remarkable influence upon the growth of medical knowledge, and without chemistry medicine could not have taken the high position it now occupies as the healing science rather than the healing art. Medicine has gained a marvellous stimulus from the discovery of synthetical methods. The artificial building up of complex compounds from simpler ones, or from the elements themselves, has proved chemistry to be one of the most useful and faithful servants in the cause of medical knowledge and advance. By this we do not mean simply that synthesis has given to the physician a list of valuable remedies—as antipyretics, hypnotics, or what may be regarded as quinine substitutes (although this is a fact of extreme importance) but rather that by means of synthesis we have been led to a better understanding, and, indeed, in many cases to an exact knowledge, of the constitution or structure of remedies. This knowledge as it grows promises to place pharmacology upon a really scientific basis. If we are not wrong, the therapy of drugs will, perhaps before long, resolve itself into a question of chemical structure. The practitioner endued with the knowledge of what the specific remedial requirements of his patient are, will be enabled to minister to those requirements by adding or omitting, so to speak, groups or radicals in the compound which are or are not requisite in the case before him. It cannot be doubted that the specific therapeutic action of a drug depends not on its composition, but on its constitution, and the more we find out about the chemical structure of remedies the more satisfactory will be their administration.

As our readers probably remember, the first important

Hosted by Google

synthesis was effected by WÖHLER some ten years before the QUEEN came to the throne. It was the synthesis of urea, which for ever destroyed the idea that the so-called organic compounds could only be built up by the life processes in the plant or animal organism. Later, FRANKLAND announced the successful synthesis of certain hydrocarbons, while recently sugar has been built up practically from its elements by FISCHER. The synthesis of conine also has been effected by LADENBURG, the first step towards the artificial preparation of that important group of bodies in medicine, the alkaloids. The modern synthetic list, however, is a never-ending one. Take, for instance, the numerous antiseptics derived from coal tar, the preparation of which would never have been suggested without a knowledge of the architecture of molecules! Antiseptic treatment is one of the medical triumphs of the Victorian era, and it was chemistry that placed these agents of healing in LISTER'S hands. The vegetable colouring matters are now prepared in the laboratory of the chemist, who, by his acumen and observation, has forestalled nature in her wonderful building-up processes. Imagine, again, life in this Jubilee year without the colours which coal-tar chemistry has placed at our disposal. It is pretty safe to say that the historical pageant on Tuesday next will owe its brilliance in a very large measure to the beautiful series of colours which the inquisitive chemist has prepared from coal tar. The colours in the procession and in the decorations will afford a striking piece of evidence of the triumphs of chemistry achieved during the QUEEN'S reign. It was in 1856 that an English chemist, PERKIN, who is still among us, prepared the first aniline dye—namely, mauveine. Then followed a crop of discoveries resulting in the wide and beautiful series of aniline colours with which we are all now familiar. From the same source (coal tar) has been derived the long list of modern remedies which are mainly of the antipyretic and antiseptic class. It is interesting to recall the fact that carbolic acid, the first antiseptic, was discovered in tar but three years before the QUEEN came to the throne. The existence of this antiseptic in coal tar led to further investigation with the happiest results. From carbolic acid was obtained by a very simple process salicylic acid, which previously was only to be obtained from natural sources, chiefly in the oil of wintergreen. Synthetic compounds, however, need to be prepared with the utmost care in order to be "physiologically pure."

Within comparatively recent years it has been established that the microbe performs the great double function in nature of both analysis and synthesis. The important bearing of this fact upon the history of disease is now one of the most remarkable acceptances of the Victorian era. The work of PASTEUR is referred to in other columns, but it may here be pointed out that PASTEUR was a chemist. His work bore on the important study of the nature of the putrefactive and fermentative processes. In both these vital processes he found that organisms were at work re-arranging the compounds presented to them and evolving sometimes simpler and sometimes more complex bodies. In putrefaction definite products now known as ptomaines, which in constitution resemble the alkaloids, were recognised. In an analogous way the products of the life processes of bacteria are now known to be the direct cause of disturbance in the economy, giving rise to the manifestations of a specific disease. The importance of bacteriology in the etiology of disease is now fully established, and it remains to be remembered that chemistry cleared the way and opened up this field of study.

Lastly, we may recall the improvements that have been effected both in the preparation and in the form of administration of drugs, improvements depending largely upon chemical advance which have secured for the practitioner an economy and an accuracy in prescribing which two decades ago were quite unknown. This alone is worthy of emphasis as one of the marked features in the progress of administrative medicine during the Victorian reign, and taken in conjunction with what we have said before as to the possible development of an application of accurate chemistry to dosage and even choice of remedy, suggests a forecast that the debt of the physician to the chemist will continue to grow larger. When again there is recorded the history of sixty years of medical achievement we believe that the teachings of chemistry will have to be still further acknowledged in throwing light upon the action of remedies, and it is reasonable to hope that the knowledge of the constitution of remedies will have become so advanced by that time as to place therapeutics on a more exact, because less empirical, basis.

THE RISE OF BACTERIOLOGY: SERUM PATHOLOGY.

To recount the progress of Bacteriology during the last sixty years would be to write practically the whole history of this branch of medical science. Before 1837 there were only a few isolated observations by LOEWENHOECK, SPALLANZANI, and SCHWANN, the latter of whom proved that the agent which brought about fermentation was a something in the air which could be destroyed by heat. Early in the reign further observations were made by HELMHOLTZ, HENLE, and others who enunciated the germ theory of disease. But the science was only laid on a firm foundation by the philosophic genius of PASTEUR, who investigated the subject of fermentation by yeast and then that of putrefaction. He showed by perfectly devised experiments that both processes were directly due to the growth of organisms which were present in the air, and that putrefaction could be indefinitely postponed if these organisms were prevented from entering the vessel in which the fluids were contained. The confirmation of these observations by a host of observers, prominent among whom were TYNDALL and LISTER in this country, gave the death-blow to the doctrine of spontaneous generation. PASTEUR also echoed HENLE'S prediction that all forms of contagious disease would ultimately prove to be due to specific organisms.

Shortly after this, in 1865, DAVAINE announced the discovery of the bacillus anthracis in the blood of animals suffering from splenic fever, and PASTEUR demonstrated that a disease among silkworms, which was threatening to destroy the silk industry, was due to an organism, and proved that by recognising the organism under the microscope and destroying the infected moths and their eggs the plague could be stamped out. Meanwhile, KOCH had been making his brilliant observations on the life-history of bacilli and the mode of obtaining pure cultures. His methods, particularly his plan of obtaining solid media, by adding gelatin to the broth, were eagerly adopted by a host of investigators, and these methods, and his criteria for deciding whether an organism found in connexion with a particular disease is the actual cause or not, are to this day those on which all observers rely. The name of KOCH will ever be remembered with that of PASTEUR as making possible the great work which has been done all over the world since their early investigations. Stimulated by the profound and philosophic teaching of PASTEUR, and by the exquisite methods of investigation brought to perfection by KOCH and his pupils, numerous pathologists in all countries at once set about the quest for the germs responsible for the various forms of disease, and for those which excite specific sorts of inflammation, and discovery after discovery rewarded their efforts. Those which have had the most practical result have been the discovery by KOCH of the tubercle bacillus, and later of the cholera bacillus; that by EBERTH of the bacillus of typhoid fever; that of diphtheria by KLEBS and LÖFFLER; and the

Hosted by Google

discovery of the plague bacillus by YERSIN. Not only has this work changed our views of the pathology of many of these diseases, but it has thrown unexpected light on the best ways of preventing their occurrence, and has been the chief cause of the importance that the subject—that of preventive medicine, hardly thought of in the pre-Victorian days—takes at the present time. Foremost among preventive measures was the introduction of "antiseptic surgery" by LISTER, who grasped the significance of PASTEUR'S teaching that septic processes were due to organisms derived from the air, and set himself to devise means whereby to exclude the organisms from

M. PASTEUR.

wounds during an operation, and also to prevent them from finding an entrance after a dressing was applied. The system did not spring into existence in a perfect state, and has undergone much modification in details of procedure since it was first brought into notice by LISTER. But the principles have remained unshaken, and have revolutionised surgical procedure, and so reduced the mortality and pain following an operation, just as anæsthetics have abolished suffering under the knife, that the terrors of surgery have been reduced to a minimum.

Not only has the study of bacteriology led to the prevention of disease, but it has also given us new and unexpected means of dealing with infective diseases, even when they have manifested themselves for some time. The first observations on this point were almost the result of an accident. PASTEUR found that the contents of a flask containing a culture of the chicken-cholera bacillus were innocuous when injected into fowls, but, to his surprise, when he injected a fresh virulent culture into these same animals he found that they were proof against the virus. Starting from this observation he laboured until by similar methods he had obtained from cultures of the anthrax bacillus a "vaccine" which has been the means of protecting thousands of sheep in France from this destructive malady. Recently similar methods have been employed by HAFFKINE to obtain a "vaccine" against cholera, and although sufficient time has not elapsed for an adequately extensive trial of the method to establish its value, the results appear to be highly promising; moreover, during the last few weeks HAFFKINE has reported the result of some inoculations in cases of plague with a "vaccine" obtained from a culture of YERSIN'S plague bacillus in ghee, the bacillus being killed by heat before inoculation. Later PASTEUR found that the virulence of a culture might be modified by various external conditions, notably by the temperature at which growth takes place, so that, if injected into an animal, while not causing an attack of the disease, it may protect against a subsequent inoculation; or may mitigate or arrest an attack even if it is not injected for some time after a virulent culture has been introduced. In this way he obtained a "vaccine" for inoculating persons who had been bitten by animals suffering from rabies, and though not an absolute safeguard it has greatly reduced the mortality from that terrible disease—hydrophobia.

In 1890 a great advance was made when it was discovered by BEHRING and KITASATO that antidotal substances, or antitoxins, could not only be produced in vessels in the laboratory, but could also be obtained in large quantities under certain circumstances in the serum of living animals. They found, in the case of the tetanus bacillus, that if a virulent culture were injected into animals which were not susceptible to tetanus, the serum of their blood had the power of neutralising the effect of a virulent dose of the poison in a susceptible animal, even after the symptoms of the disease were well established. An animal of the same species not so protected infallibly died from tetanus. In many cases this treatment has been employed towards patients suffering from tetanus, often with the happiest results. Similarly it was found that the introduction of a culture of the diphtheria bacillus into the veins of a horse, which is insusceptible to the disease, is followed by the formation of an antitoxin which can be obtained after an interval in the serum and injected without risk into the subcutaneous tissues of human subjects suffering from this serious complaint. Moreover, it has been found possible to standardise the serum so that we can prescribe the dose of antitoxin almost as accurately as that of an ordinary drug, this advance being fully chronicled in the report of THE LANCET Special Commission on the Relative Strengths of Diphtheria Antitoxic Serums.[1] It appears probable that we are only dwellers on the threshold in our application of this method to the treatment of disease.

A serum prepared from the pneumococcus has been employed in cases of pneumonia, and in several cases the painful and dangerous form of septic poisoning acquired through a "post-mortem wound" has been at once relieved by the injection of a serum prepared from the inoculation of streptococci into an immune animal. It is probable that before the end of the century we shall be in the possession of an antitoxin for the various manifestations of tubercle, while it is possible that this method will have a wider application than the relief merely of diseases due to an organised virus, as it has been shown that an antitoxin can be obtained by exactly similar methods against serpent venom and the vegetable poison "abrin." Enough has been said to show what powerful agents for the treatment of disease have been put into our hands through the study of bacteriology, but it must not be forgotten that bacteriological methods have been of the greatest value in the clinical investigation of individual cases. The recognition of the bacillus of tubercle or of diphtheria, for example, may reveal the nature of a case and lead to successful treatment. Carrying the uses of bacteriology in diagnosis further, we have the reaction which ensues when the products of the growth of bacilli, such as tuberculin and mallein, are injected. Here we have, especially in the case of horses and cattle, the most precise indications as to whether the animals are the subject of tuberculosis

[1] THE LANCET, July 18th, 1896.

Hosted by Google

or glanders or not. More recently the reaction of the blood, or of the serum, of a patient suffering from typhoid fever, promises to be of great value in clearing up the diagnosis of doubtful cases, while it opens up quite a new branch of inquiry. We refer, of course, to WIDAL'S serum test.

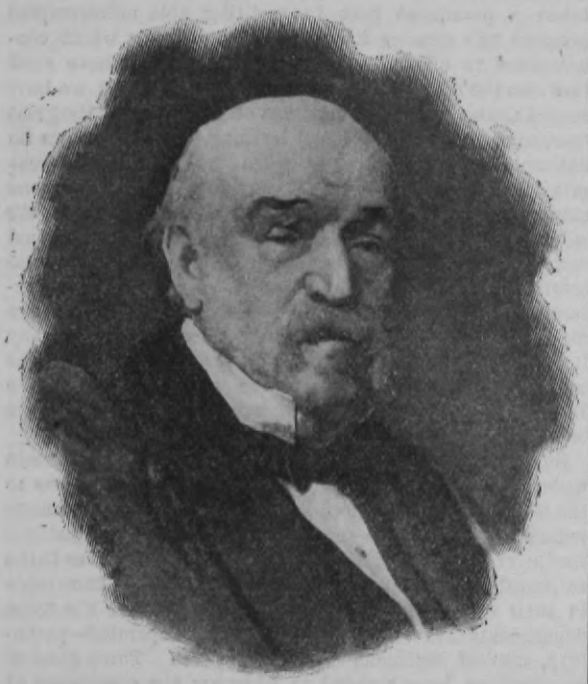
The field is an enormous one, and the harvest already reaped great beyond all expectation, but it is probable that the science of bacteriology is only in its infancy, and that those who live to see it arrive at maturity will witness greater results than we at the present day can possibly conceive.

THE ADVANCE IN ANATOMICAL LITERATURE.

THE greatest advance in our knowledge of anatomy since the accession of HER MAJESTY to the throne is marked by the thoroughness and excellence of the various leading treatises on systematic anatomy. Between 1841 and 1844 the second edition of SÖMMERING'S Anatomy was published in eight volumes, revised and amended by BISCHOFF, HENLE, HUSCKHE, THEILE, VALENTIN, VOGEL, and WAGNER; and the sixth volume of this work, which was produced under the supervision of Professor HENLE, is the high-water mark of descriptive anatomy up to that date. CRUVEILHIER'S work on Descriptive Anatomy, which was translated into English by Dr. ALEXANDER TWEEDIE in the "Library of Medicine" in 1851, and which has since passed through several editions, is even now as worthy of study as most of our more modern text-books, and, with the Descriptive Anatomy of SAPPEY, published in 1847, prove that the French anatomists were in no way behind in this branch of science. TODD and BOWMAN commenced their Cyclopædia of Anatomy and Physiology in 1835, but twenty-four years elapsed before its completion, and it remains even up to the present date the best standard work on descriptive anatomy, although its physiological and histological details have been widely enlarged and improved on. In fact, ordinary descriptive anatomy has undergone no change, although some minor details have been revised, since the first really valuable work on Practical Anatomy came into the hands of, and was made use of by, every intelligent medical student. As text-books in Human Anatomy, those of HENLE in Germany, SAPPEY in France, and QUAIN and GRAY in England are models of what scientific text-books should be, and they are all products of the Victorian era.

Topographical anatomy was practically introduced by BLONDIN about 1830, but his work attracted but little attention until the works of HYRTL and LUSCHKA demonstrated to everyone that a new departure in anatomy had to be dealt with. Frozen sections came later and improved the *technique*, so that at the hands of PIROGOFF and LEGENDRE the relative position of the structures in the limbs in their normal position became absolutely known. HIS and BRAUNE extended this method to the abdominal and thoracic viscera, and on the basis of these researches the whole science of normal topographical anatomy has been built up. The elaborate work that has been devoted to this branch of anatomy in late years is, perhaps, best shown by the beautiful photographs of the anatomy of the brain by DALTON of New York, published in 1885.

Morphological anatomy is almost a product of this century. A few isolated instances of abnormal variations in the body had been previously put on record, but no attempt to systematise them had been made. TIEDEMANN and RICHARD QUAIN the surgeon elaborately investigated the varieties of the main arteries in the human body, and this led them to some very important remarks on the ordinary procedures of operative surgery. WOOD and GRUBER'S researches, in addition to those of several other observers, have opened up the wide question as to the relation between muscular abnormalities in man and the normal arrangement of muscles in the higher vertebrates; but it is questionable if this line of inquiry has led to much lasting result, although at the time it seemed to be most promising.



MEDICINE: ITS SHARE IN THE GROWTH OF NINETEENTH CENTURY SCIENCE.

IT is not easy to realise the full extent of the changes that have been effected in the knowledge of the nature of diseases and of their more rational treatment during the sixty years covered by the reign of QUEEN VICTORIA. In almost every direction progress has been so marked that in contemplating it there is a risk of under-estimating the position which had been already attained by medicine in the opening years of the century. It is worth recalling that the first edition of WATSON'S "Lectures on the Principles and Practice of Physic" appeared in 1843 (based on the course delivered by its author at King's College in the session 1836-37), and that, marvellously as pathological science has developed since that time, those two volumes contain much that is of permanent practical value. There must be few medical men whose memories of the practice of medicine take them back to those days, which witnessed the awakening of science in all its departments. Nor should it be forgotten that modern medicine is greatly indebted for its development to the advances made in the ancillary sciences. Physics and chemistry, biology and morphology, have contributed to the fuller knowledge of animal structure and function, knowledge crowned by the researches of the physiologist. It is the application of these studies of the living body in health to that of the derangements that constitute disease which marks our era, an era that deserves to be known as that in which medicine, emerging from the thraldom of "systems" and theories, came to be placed on a rational basis and to gain a footing amongst the sciences. And as regards those who have taken a prominent part in assisting this uninterrupted progress this country has produced not a few whose contributions to clinical medicine and pathology have shed lustre on the reign, whilst during the same period we have reaped the benefits of the products of the genius of the great Continental centres of medical learning. Science knows no nationality, and it is only when we deal with great principles or root ideas that we are justified in placing one man or one nation above another; for the rest all the workers in the great edifice of knowledge may claim an equal recognition from the hands of a grateful humanity in whose service they have faithfully laboured. We ought not, therefore, in a review, however cursory, of the progress of pure medicine—the elder branch of our science—to allow any limitations, but should cheerfully recognise that all the world over there have been the same spirit and the same effort to seek out the secrets of disease, with the common object of its prevention and treatment.

Such a review may perhaps be most appropriately made under three divisions. The first would be an inquiry as to the methods and results of investigation into the intimate nature of diseases; the second as to the greater capacities for their detection and discrimination; and the third as to the enhanced power which has been gained by such knowledge in their control and management. These are the three departments into which medicine may be separated—pathology, clinical medicine, and therapeutics. Three lines of investigation have assisted in widening the conception of the nature of diseases, lines which came into operation successively and have since been pursued concurrently. They are the anatomical, the physiological, and the bacteriological. Of them, the first, dating from MORGAGNI, was the main field of pathological study at the dawn of the century, although the genius of JOHN HUNTER had foreshadowed the prominent

Hosted by Google

part which the observation of vital processes would come to take in the interpretation of morbid changes. At any rate, it would be safe to say that when the Victorian era opened the attention of pathologists was in the main confined to post-mortem dissection, and the study was rather of the effects than of the processes of disease. This study was, however, to gain a great impetus, and to have far greater significance than had hitherto been given it. The perfecting of the microscope, and the study by its means of the intimate structure of tissues and organs were about to open up an entirely new field of anatomical research. The importance of the "cell" as the ultimate element in all living things, its transformations and its powers were soon recognised, and received their fullest exposition in the memorable work of VIRCHOW on "Cellular Pathology," which appeared in the "fifties." The insight which the development of this branch of morbid anatomy, supplemented and aided by similar researches in normal anatomy and embryology, has given into the workings of disease has been enormous, so that the numerous published transactions of societies, and the text-books and monographs of this period literally teem with facts gleaned from microscopic investigation and the inferences drawn therefrom. Thus was obtained a clearer conception of the changes which accompany inflammation and repair, the degenerations, and, chief perhaps of all, the systematic and orderly analysis of new growths, not to mention the lesions which are produced in local diseases of individual organs. Nor was the older study neglected; it did not need the microscope to reveal to BRIGHT the fact that albuminuria and dropsy were associated with definite and varied lesions of the kidney, or to ADDISON that a special form of destructive inflammation of the suprarenal capsules was associated with a definite train of symptoms, including progressive pigmentation of the skin. The non-identity of typhus and typhoid fevers was established by STEWART

SIR WILLIAM JENNER.

and JENNER by an exhaustive study and comparison of gross morbid lesions with the clinical course and symptoms of continued fever; and the deep-seated changes wrought by syphilis were made known by WILKS before their minuter lesions were analysed. So has it been with many another disease which has been discriminated by careful observation; but once the distinction has been established the deeper scrutiny of the microscope has revealed still finer differences. Especially has this been the case with diseases of the nervous system, where, as we shall shortly see, clinical observation has been so fruitful of result within this epoch. Amongst the affections upon which inquiry has been especially fruitful in these years of active progress must be mentioned those diseases which depend on changes in the blood and blood-forming organs, rickets and diabetes, cretinism and myxœdema, osteitis deformans and acromegaly, to name only a few where the morbid characters are obvious and striking, but where, too, the knowledge gained from anatomical observation has been vastly supplemented by that of clinical study.

Much as has been learned by the purely anatomical method, its limitations were soon obvious to those who felt that the solution of the mystery of the living body was not to be found in the dead tissues. The application of the principles of the physiologist to the elucidation of disease processes was, however, neither so simple nor so satisfactory a line of research as the older method. Yet the expansion of knowledge upon the nature of disease which has ensued from this field of inquiry has been wide and is far from being completed. To the school of experimental pathology—in which the names of TRAUBE, the physician, and of COHNHEIM, the pathologist, stand prominently out—is owing a large part of our knowledge of the actual process of inflammation, of the derangements of the circulation, and of disordered nerve function, in which latter CHARLES BELL and MARSHALL HALL were pioneers. Here, too, must be acknowledged the light shed on the intimate processes of nutrition and nutritional disorders which are still engaging the attention of the physiological chemist, for they involve problems that are amongst the most difficult of solution. The researches of CLAUDE BERNARD and of PAVY have given us an insight into the pathology of diabetes; those of BOUCHARD and his pupils into that of uræmia and the blood states due to "self-intoxication" from defects in elimination or the absorption of poisons generated in the alimentary canal. The study of the gastric secretion is tending to a rational differentiation of the great group of the dyspepsias, whilst the chemistry of gout and rheumatism is advancing us to a more accurate perception of the *rationale* of those blood states. The recognition of the causes and effects of increased arterial tension and the philosophical views of GULL and SUTTON have done much to give breadth to our conceptions of chronic Bright's disease. The subjects of animal heat and the phenomena of fever have attracted investigators both in physiology and in pathology, with the result that many facts and theories have been harmonised, even if some of the latter have been found inadequate to explain all the former. Indeed, it would be difficult to point to any subject in which the physiological method of research has not been applied with more or less success to elucidate the phenomena of disease.

Meanwhile, however, the problem of disease has been attacked from another side—one, too, which considering its comparative newness has been almost more prolific of result than any other. When PASTEUR by his studies on fermentation and putrefaction discovered the part played therein by the operation of living organisms, it must have been far from the thoughts of the pathologist that these researches could have any bearing upon the causation of diseases. But by his investigations he, a chemist, was laying the foundations of an edifice that was to replace the less substantial fabrics of all the pathologists, and he lived to see it attain dimensions that bid fair to embrace the whole range of infective diseases. There is no subject in the whole history of medicine which has more rapidly attained to an unassailable position in so short a space

Hosted by Google

of time than this of the explanation of infective diseases and inflammation by the intervention of bacterial parasites. The science of bacteriology has grown up under the eyes of the present generation and has revolutionised our conceptions of the nature of disease. The speculations of HALLIER and HENLE upon the germs of disease, the theories as to contagion and infection which engrossed attention during the first half of the period of which we are speaking, have in the latter half—nay, indeed, in an even briefer space—been dispelled by the proven facts of bacteriological investigation, since the day that KOCH conclusively demonstrated the pathogenic properties of the anthrax bacillus or OBERMEIER proved the dependence of relapsing fever on the spirillum that bears his name. There is no need here to recount the steady progress to which this pursuit of minute cryptogamic studies has led us in relation to disease; but without a doubt it may be affirmed that in this pursuit, and in all that flows from it, we have the most striking instance of the gains acquired by medicine in this century, and have entered on a field of research which is by no means exhausted.

Meanwhile, if the nature of disease and its causation have become plainer and been placed on a more scientific basis, it must be admitted that *pari passu* there have been most notable additions to the methods of clinical investigation, which have vastly extended the powers of accurate diagnosis. This has been mainly effected by the invention of scientific instruments and appliances, nearly all of which were subsequent to the time at which our survey opens. For sixty years ago but a short time had elapsed since LAENNEC'S genius had demonstrated the new field of observation opened by the use of the stethoscope—an instrument which was then only appreciated by the few, perhaps even despised by the many. In this country we cannot forget how much is owing to C. J. B. WILLIAMS, HUGHES BENNETT, and WALSHE for their studies on the methodical examination of the chest by physical exploration. The interpretation of signs would have been of small service had it not been combined with the more accurate knowledge of the morbid changes in heart and lungs which gave rise to these phenomena. Thus as knowledge grew in the one direction it was helpful to progress in the other, and much as those who claim to be "practical" rather than "scientific" men may affect to ignore the teachings of pathology, it is clear that no one can be eminent in clinical medicine who has not laid a good foundation in pathology. As the years rolled by we find additions made to the clinical armamentaria, such as the thermometer (first used clinically in 1850), the ophthalmoscope (1851), the laryngoscope (1857), whilst the aid given by electro-physiology in diagnosis forms another of the remarkable developments undergone in the study of diseases of the nervous system. Indeed, there is no department which has developed to so great an extent during these two generations as this of neurology. And much of this advance has been owing to thorough and minute clinical observation, which has often led the way for physiology to follow in interpreting the functions of nerve and muscle. The localisation of cerebral functions, the discrimination of the "system diseases" of the spinal cord, the differentiation of spasmodic muscular affections and of the forms of muscular atrophy, the study of neuritis,—these, and many more are the fruits of the clinical medicine of our day, supplemented by pathological and physiological research. We are proud to think that in this study so much has been done by the fellow countrymen of BELL, MARSHALL HALL, and ABERCROMBIE, for where would neurological science have been had not HUGHLINGS JACKSON, REYNOLDS, GOWERS, FERRIER, CHARLTON BASTIAN, BUZZARD, and many others made their invaluable studies on the subject? There is no need to dwell on the other means which have been freely used for the study of disease—the clinical use of the microscope and of the test-tube, the invention of the sphygmograph and cardiograph, and other instruments imported to bedside observation from the physiological laboratory. Enough has been said to show that no means have been left untried to procure greater accuracy in diagnosis and to bring to bear on the investigation of disease every available resource which thought and ingenuity can suggest. Thus has it happened that our present knowledge of the nature and processes of diseases is of far deeper extent and wider range than it was when the QUEEN was called to the throne.

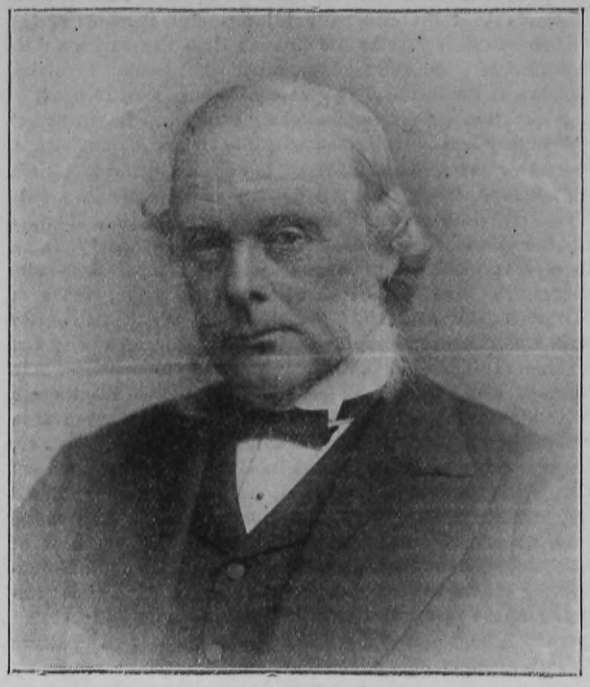
It remains to inquire whether there has been a similar advance in the art of healing. In answer to this it cannot be forgotten that perhaps the chief gain to medicine has not been so much in the direction of the actual treatment of disease as in that of its prevention, a line of practice that has naturally followed upon the tracking out of the causes of disease. The Victorian era has been characterised by the rise and development of sanitary science, and nations have learnt that their principal care lies in the exercise of forethought and the wide application of hygienic principles. Cleanliness and purity of air and water and of food and drink, the more wholesome construction of dwellings, the avoidance of overcrowding, the practice of measures of isolation, the control of unhealthy occupations, the better management of factories, and many another effort to attain conditions which tend to diminish disease, have received increasing attention. And it is in this country that the principles of public health were earliest recognised and put to practical use. Surely this is in itself an achievement which marks an epoch in the history of medicine, with which the names of CHADWICK, of SIMON, and of PARKES will be always associated. And with these efforts to prevent disease on the large scale ought we not also to point to the praiseworthy exertions of those who have striven by precept and example to inculcate a knowledge of the laws of health among the people, and thereby to diminish the suffering and death which ensue on the neglect of these laws? Hygiene, public and personal, is the keynote of modern endeavour to limit the ravages of disease, and it is owing primarily to the medical profession that the gospel of prevention has been so widely spread. If we turn from this—the main gain of enlightened medicine—to the progress made in the actual treatment of diseases, we cannot fail to be struck by the change that has been effected within our day. Such a revolution of ideas as that which caused the abolition of wholesale venesection and of the lowering treatment of fever is not to be explained by caprice or fashion. There has, on the contrary, been a growing effort to place medical therapeutics upon a rational basis, to determine with accuracy the action of drugs, and to limit their prescription to definite objects. Thus we witness the gradual emergence from the empirical to the scientific, the recognition of the limits of physic, and the introduction of methods other than those in which drugs are concerned. Doubtless this altered standpoint is largely due to profounder knowledge of the lesions that it is sought to remedy, but it is equally to be found in the domain of so-called functional as well as of organic disease. Moreover we have seen within quite recent days the direct application of more exact knowledge of the nature of disease to measures for its mitigation or remedy, as in the remarkable result of the thyroid treatment of myxœdema, the Pasteurian treatment of hydrophobia, and the antitoxin treatment of diphtheria. In these and analogous departures there is evidence that the study of therapeutics is becoming more scientific and less empirical, more rational and less a matter of chance or guesswork than it has ever been before. Yet a few years and the nineteenth century will have reached its term.

Hosted by Google

Those who essay to record its achievements will find no chapter more interesting than that which deals with medicine. To detail the progress made in each of its departments would amount to the compilation of a cyclopædia, but whoever undertakes the task will find that the most progress and the greatest gains have been made and won in that portion of the century that corresponds to the glorious reign of our illustrious Sovereign; for just as the Elizabethan era was characterised by triumphs in letters and learning, the Victorian era will be known as that wherein science established its dominion and lent its powerful aid to the cause of humanity.

SURGERY: ITS REMARKABLE PROGRESS DURING THE REIGN.

GREAT as has been the progress in so many of the arts and sciences during the present reign, yet surely in few has so much advance been made as in surgery. Not that we would for a moment suggest that surgery had not progressed before 1837, for then there were many surgeons living who had done much for the advancement of their art. Taking London alone we find the names of many who will long be remembered as worthy exponents of surgery, and all of whom have done something to put it on a more scientific basis. To mention only a few, there were ASTLEY COOPER, JOHN SCOTT, CURLING, WILLIAM LAWRENCE, EARLE, STANLEY, SKEY, JAMES WARDROP, SAMUEL COOPER, LISTON, RICHARD QUAIN, the author of the Anatomy of the Arteries, GUTHRIE, BENJAMIN BRODIE, and HAWKINS. As each name strikes the eye it calls up some important surgical fact, some interesting surgical method, superseded, perhaps, now, but still of value as indicative of the unceasing progress which takes place in surgery. Yet though there were indeed giants of surgery in those days, were a surgeon of to-day to return to a ward or an operating theatre of 1837 he would feel overwhelmed by the immense differences between the practice of those days and of our own.



If we were asked to indicate what had done most to bring about the change from those far-off times to these latter days, we should have no hesitation in saying that two things had contributed more than all others to the difference, and these two things are anæsthetics and antiseptic surgery. In operations before the introduction of anæsthetics manipulative dexterity was one of the greatest virtues which a surgeon could possess, for rapidity of operation was essential when the patient was fully conscious of every stroke of the knife; and so surgeons such as FERGUSSON and LISTON arose, whose manual skill was a marvel to their contemporaries. Amputation of the thigh was performed in less than two minutes, and five minutes amply sufficed for extraction of a stone from the bladder by the lateral method. Such celerity in the performance of major operations is now practically a thing of the past, it is no longer needed, and careful dissection has replaced the lightning movements then in vogue; but it is by no means certain that surgical practice has not gone too far in the opposite direction, and we cannot but think that in many cases the "shock" of an operation would be materially lessened by a more rapid system of operating.

Though attempts had been made from the earliest times to prevent or diminish in some degree at least the pain in surgical operations, yet the results must have been unsatisfactory, as the methods fell quickly into disuse and were replaced by others equally unavailing. In 1844 an American dentist, HORACE WELLS, of Hartford, Connecticut, inhaled nitrous oxide gas in order that he might have a tooth extracted, and finding the attempt successful in his own case he employed the method with varying success in other similar cases. Two years later W. J. G. MORTON, of Boston, employed the vapour of ether, "sulphuric ether" as it was called, for relieving pain in tooth extraction, and a little later he administered it in the Massachusetts General Hospital to a patient who was about to have a tumour removed from the neck. The practice quickly spread, and in December of the same year (1846), at the University College Hospital, London, LISTON amputated the thigh of a patient under the influence of ether, but as he had little faith in its efficacy he operated with his usual rapidity. A year later chloroform was introduced by SIMPSON of Edinburgh, and for a long time replaced ether as an anæsthetic in this country; but the frequency of the occurrence of death during chloroform narcosis has lead in England to a return to ether as the ordinary anæsthetic. In Scotland, however, chloroform is still the agent most employed. Nor should the benefits of local anæsthesia be overlooked. The first form used was the result of cold produced by ether spray; it was introduced by B. W. RICHARDSON in 1865. The ethyl chloride spray, a much more recent introduction, is also much used; but of all local anæsthetics by far the most valuable is cocaine, which was not employed till 1884, when it was introduced by KÖLLER, of Vienna, though it was discovered in 1859. It is readily absorbed by all mucous membranes, but unfortunately it cannot pass through the epithelial layer of the skin, so that its use is somewhat restricted; but in many operations upon the eye cocaine has completely replaced general anæsthetics.

The other great agent in the extension and advancement of surgery has been the systematic practice of asepsis. Sixty years ago the treatment of operation wounds varied a great deal. In LISTON'S practice the flaps were allowed to remain apart for three or four hours so that the surfaces became glazed with adherent exudation before they were drawn together, and healing by first intention by no means rarely followed, but suppuration was unfortunately the rule, and many weeks had to pass by before healing was complete. Another method with very similar results was the "open treatment" of BARTSCHER and VEZIN (1856). In this the wound was covered only with a piece of linen, and in a few weeks healing was complete. In this way VOLKMANN, of Halle, treated all his amputation wounds during the war of 1866. Perhaps the most usual treatment was by irrigation or immersion, and some surgeons—as VALETTE, of Lyons, in 1855—added various antiseptic substances, such as alcohol, benzine, and creosote, to the water. Though, as in this case, substances possessing antiseptic properties had been employed for many years in the treatment of wounds, yet the antiseptic method of LISTER was really an entirely new departure. The researches of PASTEUR and TYNDALL had proved the almost universal presence of organisms giving rise to putrefaction, and also that if these germs were excluded decomposition could not occur. LISTER applied these facts to the treatment of wounds, and conclusively proved that in the absence of septic organisms there was no formation of pus, and wounds healed always by first intention. The publication of such satisfactory results in 1870 was rapidly followed by the general adoption of the "Listerian" method. At first there was a certain amount of opposition, and some surgeons declined to turn aside from the paths they had trodden so long; but these were exceptions, and practically the whole surgical world adopted the new process with acclamation. The effect on the prevalence of all forms of septic diseases—such as erysipelas, septicæmia, and pyæmia—was most striking. The testimony of NUSSBAUM, of Munich, is that "during sixteen years the hospital was never free from pyæmia for a single month, and yet it suddenly disappeared on the introduction of the Listerian method." At first the antiseptic treatment consisted of a most elaborate ceremonial, and with slight modifications it continued very much the same for some years, but ideas slowly began to change with regard to the prevalence of septic micro-organisms in the air. It was found that the danger of germs falling into the

Hosted by Google

wound during an operation was much less than had been imagined, and so the "spray" was given up. More recently still it has been recognised that unless germs have already made an entrance there is no need to employ any "antiseptic" in the wound; it is sufficient if everything that comes in contact with the tissues is aseptic.

LORD LISTER.

Thus the "aseptic" treatment of wounds has arisen and in great part has replaced the antiseptic treatment, though it is really only a further extension of the same idea. When "asepsis" is carried out thoroughly and conscientiously every wound heals absolutely by first intention, and suppuration in even the slightest degree is banished.

The progress which has taken place in British surgery during the last sixty years cannot be dissociated from the progress of surgery in other countries. There is no surgery exclusively British, for surgery is cosmopolitan, though there are slight differences between surgery as it is practised in Britain and as it is practised in France; but we can also find slight differences in surgical practice between London and—say—Liverpool, and these differences are not in any way inconsistent with the truth that surgery is one and indivisible. In considering, therefore, the progress of surgery our view must include the whole civilised world. Amputations formed the branch of surgery in which perhaps the greatest success had been attained in days anterior to the present era. The circular method and the flap method with various modifications were well known, but the "modified circular" amputation, which LISTON introduced in 1839, was a distinct advance, and it is still extensively practised. In 1853 TEALE, of Leeds, devised his rectangular flap method; yet, although it possesses many meritorious features, it is only occasionally used, as it sacrifices a great extent of the limb. The special amputations which have been introduced are more numerous. Among them may be mentioned SYME'S amputation at the ankle-joint, in which he reduced to a regular operation what had been done by many for a long time previously. PIROGOFF'S modification of SYME'S operation is also worthy of notice. Amputation through or above the condyles of the femur was first practised as early as 1845 by JAMES SYME, but it was brought more prominently into notice by CARDEN, of Worcester, in 1864; GRITTI, of Milan, in 1857 introduced the retention of the patella after removal of its articular surface, and W. STOKES in 1870 still further improved the operation. The results of amputation at the hip-joint are now much better than they used to be, and this in great part is due to the diminution of the shock by the employment of the method devised by FURNEAUX JORDAN. In gunshot wounds far better results are now attainable. It has not very long been recognised that in many cases a gunshot wound is aseptic, and that many will heal almost by first intention if they are not injudiciously probed, and many joints traversed by a bullet are now saved by antiseptic treatment in which formerly amputation would have been performed. The increased velocity of modern projectiles has led to greater splintering of the bone, but our improved methods of dressing such wounds have more than compensated for the increased damage done. The great diminution in the diameter of the bullet has been made too recently to enable decided opinions to be expressed as to the effect on the surgery of gunshot wounds.

In the treatment of hæmorrhage during the period we are considering many decided advances have been made. Artery forceps and the ligature were in ordinary use in 1837; torsion was also sometimes employed, and though it has been, and still is, much used for small vessels, yet it has never to any real extent displaced the ligature for the occlusion of large vessels. Forcipressure, or the seizure of the end of the vessel in a powerful pair of compressing forceps, was introduced by SPENCER WELLS, and has also been employed by KOEBERLÉ and PÉAN. It is now but little employed, though the forceps devised for the purpose are those chiefly used now for the ligature or torsion of arteries. Absorbable ligatures, though used to a very slight extent by ASTLEY COOPER, have only been frequently employed since they were re-introduced by LISTER as a part of his antiseptic treatment.

A great advance in the temporary arrest of bleeding was made by the introduction of the elastic-tube tourniquet by ESMARCH, of Kiel, in 1870.

The treatment of aneurysm by compression of the supplying artery was introduced by the Dublin surgeons, especially HUTTON, BELLINGHAM, TUFNELL, and CARTE; and the tourniquet devised by the last of these, providing, as it does, an elastic pressure, is still the form most commonly employed for instrumental compression. Digital compression was first employed by VANZETTI, of Kharkof, in 1846, and later by KNIGHT, of Newhaven, U.S.A., in 1848. It is now very widely and successfully used.

The very excellent results we now obtain after suturing of nerves, whether primary or secondary, make it difficult to believe that it is a comparatively recent introduction, having been first performed by WEIR MITCHELL; he was followed by NÉLATON, LANGIER, LANGENBECH, HOLMES, MACCORMAC, and many others, and it is now an ordinary procedure. Nerve-grafting, also, though not so uniformly successful as suture of nerves, in some cases gives very satisfactory results.

For the treatment of fractures numerous splints have been devised, but of them all the most useful is undoubtedly that formed by plaster of Paris. In its original form the plaster was rubbed into the meshes of a coarse muslin bandage, but of late years the Bavarian splint, or the modified Bavarian splint, with which CROFT'S name is usually associated, has been more commonly employed. The original form, however, is still used, especially for SAYRE'S plaster jacket.

Compound fractures are no longer dreaded by surgeons as they once were, for antiseptic treatment has almost entirely robbed them of the dangers they possessed.

In fracture of the patella wiring has become almost the

Hosted by Google

rule with many surgeons, and the results on the whole justify this mode of treatment. Though it had been tried many years ago it failed on account of sepsis, and therefore it was not until it was employed with antiseptic precautions by HECTOR CAMERON, of Glasgow, in 1877 that it became a satisfactory method of treatment.

In dislocations the use of anæsthetics has rendered the replacement of the displaced bone an easy and simple procedure in most cases, and especially has reduction been aided by the scientific methods of inducing the head of the bone to retrace its steps and pass through the torn capsule at the spot where it came out. Though manipulation was employed many years ago it was not until H. J. BIGELOW, of Harvard, demonstrated its *rationale* in dislocation of the hip that the method was at all extensively used.

Malignant growths are now removed with much greater freedom than formerly, and to this must be attributed the greatly improved results which are obtained, recurrence being decidedly rarer than it was. Though the excisional surgery of the joints was not absolutely unknown in the eighteenth century, and though LISTON had excised the elbow-joint as early as 1821, yet it was not until FERGUSSON performed excision of the hip-joint in 1850 that the operation received general support. For many years excision was applied to most of the joints of the limbs, but of late years it is by no means so extensively practised. It has been in part replaced by erasion or arthrectomy, and in other cases by drainage of the joint the surgeon succeeds in obtaining a cure. Erasion was first performed in England by WRIGHT, of Manchester, in 1881; it is on the whole more applicable to the knee, where strength is required, than to the elbow, where the attainment of mobility should be the first consideration.

The surgical treatment of the bony deformities of the lower limbs resulting from rickets or ankylosis is practically entirely modern. Genu valgum was treated by DELORE, of Lyons, by forcibly straightening the limb; the results were somewhat uncertain, and it has been replaced in great part by osteotomy. In 1875 ANNANDALE sawed off the inner condyle of the femur, and a year later OGSTON did the same operation subcutaneously. In 1878 MACEWEN, after practising section of the inner condyle, chiselled through the bone above the epiphyseal line, and this is the method now employed. W. ADAMS first performed his operation for ankylosis of the hip-joint of subcutaneous division of the neck of the femur in 1869, and F. J. GANT'S method soon followed, the femur being divided below the trochanters. The removal of an enlarged thyroid gland had been practised so far back as 1820, but the result was so unsatisfactory from hæmorrhage and septic infection that it fell into disuse. Since 1870, however, the operation has become fairly common, especially in Switzerland, where the prevalence of bronchocele is so great, KOCHER, of Berne, having had several hundred cases with an insignificant mortality. It was not long, however, after total extirpation of a goitre had become a frequent operation before it was noticed that most of the patients underwent a curious derangement of the general health. The resemblance of the symptoms to myxœdema described by GULL in 1873 was soon observed, and it was seen that these symptoms were due to the absence of the thyroid gland; since then surgeons have not ventured to remove more than a part of the organ. In many cases, especially recently, it has not been found necessary to do more than enucleate an adenoma from amongst the gland substance.

It is in the surgery of the abdomen that the greatest advance has been made. At the beginning of the era there was no surgery of the abdomen; wounds involving the peritoneum were looked upon as almost necessarily fatal; and even though in the early years of the century, both in England and in America, the operation of ovariotomy was occasionally performed, yet it was not until 1857 that it was fully recognised as justifiable, and this was undoubtedly due to SPENCER WELLS. The antiseptic treatment has also materially assisted the extension of ovariotomy. The knowledge gained in this operation, especially after the introduction of antiseptics, led naturally to attempts to treat surgically injuries and diseases of the abdominal viscera. At the present time the surgeon does not hesitate to deal with stabs and gunshot wounds involving the bowel, for suture will give a good chance of recovery if the operation has not been too long delayed. Laceration of the kidney and spleen is successfully treated by excision of the torn viscus. In rupture of the stomach and intestines also laparotomy gives good results, and the results would be better still if it were possible to operate earlier. Rupture of the bladder, at one time almost certainly fatal, is now frequently successfully treated by laparotomy and suture, the two earliest successful cases being those of WILLIAM MACCORMAC. Flushing the peritoneal cavity with a mild antiseptic or sterilised water is in many cases of abdominal operation an important aid to success. In disease, also, of the abdominal viscera the results are almost as satisfactory. Pylorectomy for malignant disease was suggested by BILLROTH in 1877, but the first two cases, performed by PÉAN in 1879 and by RYDYGIER in 1880, ended fatally, and the first successful case was that performed by BILLROTH in 1831. The operation will always be rare, as but few cases are suitable for it. In cases of malignant disease of the pylorus in which the neighbouring parts are so implicated that excision is impossible the palliative treatment by gastro-jejunostomy is available, and in some cases enables a patient to survive in comfort for several months. There are many other operations on the abdomen which we can only mention, such as the operations for abscess and for hydatid of the liver (the latter first performed by LINDEMANN of Hanover); cholecystotomy, for a distended gall-bladder; removal of a gall-stone from the cystic duct, suggested by THUDICHUM in 1859, performed by MARION SIMS and by LAWSON TAIT in 1878; choledochotomy, first performed by KUMMELL in 1890 and later by KNOWSLEY THORNTON, VOIGT, KORTE, ABBÉ, and others; and cholecystenterostomy, suggested by WILLETT in 1886, and first performed in England by MAYO ROBSON. The surgical treatment of acute intestinal obstruction gives very satisfactory results, laparotomy being performed and the cause of the obstruction removed. For chronic obstruction lumbar colotomy was revived in 1839 by AMUSSAT, but during the last few years the far older operation of LITTRÉ—namely, inguinal colotomy—has been reintroduced, and is now the operation usually performed.

For the radical cure of inguinal hernia a large number of operations have been employed. Previously to the introduction of the antiseptic method the operators attempted to perform a cure without making any incision; the chief methods employed were those of C. W. WUTZER, of Bonn, introduced in 1838, and of JOHN WOOD; the latter was by far more commonly employed; but the open method is the only one used at present. The operations now in use are very numerous, and have been introduced by LISTER, ANNANDALE, MITCHELL BANKS, CZERNY, BALL (1887), MACEWEN, HALSTEAD (1890), and BASSINI (1890).

CHESELDEN'S lateral operation of lithotomy continued up to recent years to be the chief method of removing a stone from the bladder, but it is now only rarely performed. So far as cutting methods are concerned the revived suprapubic operation is chiefly used, but the same operation is still more frequently performed for exploring the bladder and for removal of growths of the bladder and prostate. Lateral lithotomy has chiefly been replaced by lithotrity.

Hosted by Google

The method practised by CIVIALE in 1824, and improved by FERGUSSON, SKEY, and HENRY THOMPSON, came to be the method of treatment for selected cases of vesical calculi; but it was not until 1878, when BIGELOW introduced litholapaxy or lithotrity at one sitting, that lithotrity became the chief method of dealing with stones of all sizes. In 1886 KEEGAN showed that children were suitable cases for lithotrity. The introduction by LEITER of the cystoscope has greatly facilitated the diagnosis and treatment of diseases of the bladder.

In the surgery of the brain very great progress has been made. No longer are fractures of the vertex of the skull considered to be of especially bad prognosis, for with care and antiseptic treatment they usually heal readily; but it is especially in injuries and diseases of the brain, where the localisation of the lesion would formerly have been impossible, that we can appreciate most the advance which has been made. There is still a large portion of the cortex the function of which is unknown to us, but disease of most parts of the brain declares clearly its locality by the symptoms and signs to which it gives rise. As a result of this knowledge surgeons have been much more ready of late years to explore the cavity of the skull. In 1883 MACEWEN, of Glasgow, trephined successfully for hæmorrhage; and later in the same year he removed a soft mass from the Rolandic area. GODLEE, in 1884, removed a glioma from the position in which its presence had been diagnosed. Others who have done much work in this field are VICTOR HORSLEY and LUCAS CHAMPIONNIÈRE.

Though a form of the laryngoscope was invented in 1829, yet it was not until 1857 that a useful laryngoscope was devised by CZERMAK. Of the various operations which have been performed on the larynx space does not allow us to speak, but we may mention that excision of the larynx was first performed in 1866 by P. HERON WATSON. He was followed in 1873 by BILLROTH. Amongst the recent additions to aids to diagnosis none can compare in importance with the ROENTGEN rays, which were first described in January, 1896; there can be but little doubt that their usefulness will increase, and even at present they are of extreme value.

MIDWIFERY: THE PART PLAYED BY ANÆSTHETICS AND ANTISEPTICS.

THE changes that have taken place in obstetric medicine during the past sixty years, both in the region of theory and as regards the details of practice, are, as everyone knows, in most directions considerable, and in some directions even wonderful. To chronicle these changes with any degree of completeness would necessarily require several volumes, since they could be only fully dealt with by making an abstract of all the works on midwifery and gynæcology, text-books, monographs, pamphlets, and current literature that have been written on these subjects during the period under review. Here we shall only attempt to sketch in the merest outline some of the more important alterations that have occurred. We say advisedly "alterations," since, with all the desire in the world to view matters from a judicial standpoint, we cannot altogether hope to free ourselves entirely from the bias of our own day. Some of the alterations that have occurred in both midwifery and gynæcology since the year 1837 have been regarded at one time as changes in the direction of true progress and at another time, and even by the same generation, as deviations from the real highway into by-paths that, after promising well for a time, led backwards into the darkness which it was hoped had been left behind. In some things, after all allowance has been made for the tendency of each generation to regard itself as superior in knowledge and skill to those that have preceded it, there can be no doubt that real progress has been made, while it is not impossible that in some others the appearance of progress has been fallacious; and it may be that the wider knowledge and larger experience of those that are to come after us will lead them to the conclusion that the authorities of sixty years ago were in some ways not so far wrong after all. We have only to turn for a moment to the region of art to find convincing proof that the lapse of time is not necessarily equivalent to progress, and that indeed the knowledge and skill of to-day may in certain directions be immeasurably inferior to that of, say, a hundred years ago. Such arts as the production of certain kinds of china and of silverwork are good examples of what we mean. As to china, some of the methods and knowledge familiar to many not so very long ago have been totally lost, and the silver-work of the modern workman, with all his advantages and School Board education, is poor indeed compared to what his great-grandfather, who without, very likely, being able to write was in many ways an artist instead of a mere workman, was able to produce. The process by which the practitioner of sixty years ago was evolved was essentially different from that which produces the practitioner of to-day. The latter is no doubt in many respects the better man; but probably something that pertained to his predecessor has had to be sacrificed in order to secure this superiority.

After these preliminary reflections we may come to matters of detail. The changes in the department of midwifery have not been so tremendous and striking as those in gynæcology, no doubt because midwifery is of necessity such a very ancient art. In midwifery, at all events, we do not think we can find any indication of ground having been lost. If we regard the matter from the standpoint of a woman who is pregnant at the present time as compared with that of a woman similarly situated in 1837 the former is undoubtedly in a more favourable position. We should say that should the pregnancy happen to be extra-uterine the advantage of living in 1897 rather than in 1837 is so great that probably no one would care to dispute it. In a standard text-book published in 1841 extra-uterine pregnancy is spoken of as follows:—"This singular deviation from the usual course of conception is fortunately of rare occurrence, for few cases terminate favourably. If it be in the Fallopian tube ..... the patient usually dies from internal hæmorrhage." Modern investigation has, however, shown that cases of extra-uterine pregnancy are by no means so uncommon as was formerly supposed, and that even when a tubal pregnancy has ruptured, causing intra-peritoneal hæmorrhage, the case is very amenable to operative treatment, if seen in time. Many cases have now been recorded where a definite diagnosis of tubal pregnancy has been made before rupture, and where the gravid tube has been successfully removed. There is, of course, in the works on midwifery contemporary with that just referred to nothing to be found on the subject of antiseptics or anæsthetics. We should regard the application of the antiseptic principle to midwifery as the greatest improvement that has been made in obstetric practice within the last sixty years. When it is fully understood and faithfully employed deaths from puerperal fever may be completely or almost completely avoided, as the practice of our best-managed lying-in hospitals has sufficiently shown. Even at the present day, however, in general practice it would appear from the statistics recently published by CULLINGWORTH that puerperal fever is still responsible for a relatively high percentage of fatalities which, it is to be hoped, may be prevented as the details of the antiseptic principle come to be more universally adopted. As regards puerperal fever the same authority already quoted writing in 1841 says:—"But we now come to a source of danger which follows the most favourable as well as unfavourable labours—which is extremely varied in its nature, fatal in

Hosted by Google

its effects, and (what renders it so peculiarly formidable) by no means uncommon in its occurrence. Of all the dangers to which a lying-in woman is exposed puerperal fever is by far the most to be dreaded; there are few or no difficulties during parturition which the practitioner has to contend with that can be compared to it; there are none in which he is frequently made to feel so helpless and his various means of treatment so utterly inefficacious; certain it is that puerperal fever in its worst forms has occasionally committed such ravages among patients of this class as to rival in destructiveness the most malignant pestilences with which the human race has been afflicted." With this obviously true picture of the state of things in 1841 before us, it is surely the most noteworthy achievement in obstetric practice of the last sixty years that the nature of this pestilence has been arrived at, sufficiently at least to enable us to prevent its occurrence provided the necessary precautions, which are now well known, be observed.

As regards phlegmasia dolens, or rather as it is there given "phlegmatia dolens," we quote from the same authority (1841): "Phlegmatia dolens rarely or never proves fatal of itself; the patient either dies in consequence of the puerperal fever which has preceded or attended the affection, or from the system gradually sinking under the injury which it has sustained." Nothing was apparently known at that time of the connexion between phlegmasia dolens and pulmonary embolism.

To sum up the matter, broadly speaking the midwifery of sixty years ago did not differ so very materially from the midwifery of to-day, except—and the exceptions are of the greatest importance—that it was conducted without the assistance of anæthesia and without the employment of antiseptics.

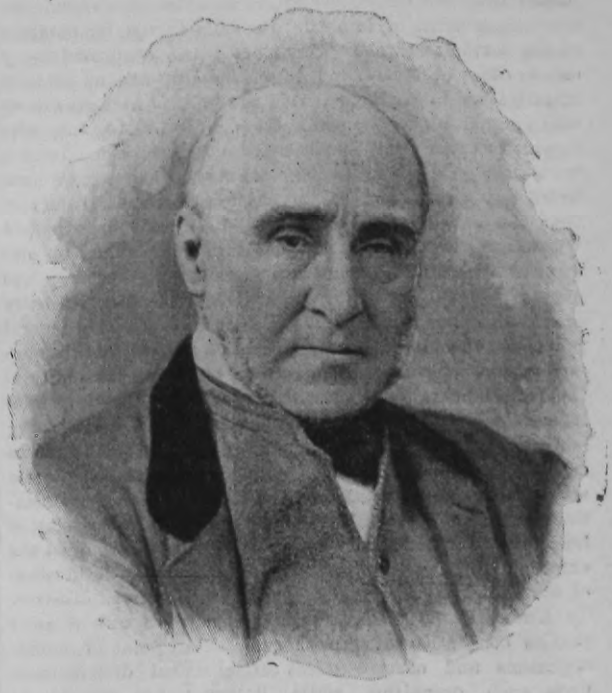
SIR JAMES SIMPSON.[1]

It is when we come to consider the progress of gynæcology during the period under review that we are confronted with changes of the most striking kind. Its progress has been marked, however, by many false starts. Theories as to the causation of many of the diseases peculiar to women have been advanced, have become rapidly fashionable, have dominated practice for a time, and have then been proved unsound and have disappeared into a well-merited oblivion. There is, for instance, the period when gynæcological practice was largely influenced by the belief that the so-called "ulceration" of the cervix was accountable for most of the symptoms complained of in relation to the pelvic organs. JOHN WILLIAMS has drawn a vivid picture of the state of things that prevailed about this time. He says: "During my early student days women suffered mainly from two diseases—ulceration of the cervix, which was rubbed weekly with nitrate of silver, and stricture of the cervix, which was dilated with bougies at similar intervals." Then there came the time when the malposition, so-called, of the uterus was supposed to be the key to a right understanding of the majority of women's ailments. The uterus was considered to be pathologically flexed or "verted" in this or that direction, and instruments innumerable were invented and used to correct the displacement. The worst offenders in this class were those who held strong views as to the importance of flexions, and carried their opinions to the logical conclusion in practice by introducing a rigid stem into the cavity of the uterus. They were more mischievous than the pessaries, merely invented for insertion into the vagina. The latter, for the most part, merely acted as foreign bodies that did little harm, if they did no good. But the intra-uterine stems were a source of actual danger to those unhappy enough to be condemned to wear them. Modern investigation has shown that the so-called "ulceration" of the cervix (by which is understood the various forms of erosion) occupies a position of little or no pathological importance, and that the uterus may be allowed to have a very considerable choice as to the situation it may occupy without this freedom of choice in any way acting to the prejudice of its possessor.

It is undoubtedly in the direction of the surgical treatment of the graver diseases peculiar to women that the greatest triumphs have been won during the last sixty years. The rise and progress of ovariotomy till it has come to its present position afford the most remarkable instance in this category. The treatment of cases of ovarian tumour is described in a standard work published in the year 1844 as follows: "Here then are the different modes of treatment recommended in ovarian dropsy: the abstraction of the water with the cautions before described; the extirpation of the ovary in the earlier and later periods of its growth; the removal of a circular piece of the cyst so as to lay open the cyst into the peritoneum; and the prevention of the dilatation and growth by early paracentesis. In the present ill-success of our practice all these operations are well worth your consideration; and if you can bring one of them to such perfection as to cure some of the unhappy individuals who now fall victims of the disease, you will indeed be conferring an invaluable good on the fairest and least offending part of our species." Which of these operations has been brought to the perfection just mentioned is now a matter of common knowledge; and all honour to those whose work established it in its present position. In the treatment of cancer of the uterus practice has also undergone a revolution during the past sixty years. In a standard authority published at the beginning of this period we find both excision of the cervix (the vaginal portion only) and removal of the whole uterus mentioned as possible forms of treatment. The mortality of both operations at that time was frightful. Nineteen cases of extirpation of the uterus are mentioned, of which sixteen died; and it is further stated on the authority of VELPEAU that the operation had been performed twenty-one times in twenty years, and that in not one of the cases was there any permanent benefit. The changes that have occurred since then in the results of such operations are sufficiently familiar to our readers. While the success of

[1] Vignetted by permission from a woodcut in the "Practitioner."

Hosted by Google



surgical treatment in the cases just referred to has been a matter for the warmest congratulation, it must not be forgotten that there have been drawbacks attending it. The success of ovariotomy has undoubtedly led to the removal of ovaries and uterine appendages in cases where such an operation could not be justified in the opinion of men of moderate views. The measure of safety introduced into all operations by the observance of asepsis has undoubtedly had a tendency to cause a multiplication of operations both major and minor in gynæcology, some of which are regarded by competent observers as of doubtful utility. Probably such a result is the necessary consequence of the enthusiasm engendered by every successful movement—and it may be hoped that the lapse of time will tend to correct any undue activity in the direction indicated.

To sum up, as regards gynæcological progress during the last sixty years in the direction of treatment, the most prominent achievements have been the establishment of ovariotomy and of vaginal hysterectomy, omitting minor operations, while in the way of diagnosis, the improvement of the speculum, the invention of the uterine sound, the introduction of means for dilatation of the cervix uteri in order to examine the endometrium, and the bimanual method for examining the condition of the pelvic organs, stand out as the chief gains to be recorded. The accoucheur of to-day can hardly imagine what his practice would be without anæsthetics and without antiseptics, and similarly the gynæcologist finds a difficulty in realising what his art must have been without these, and with practically no way of investigating his cases except by digital examination of the vagina. Among the instruments that it would seem difficult for any modern operator to dispense with, we think SPENCER WELLS'S artery forceps should certainly be named.

PREVENTIVE MEDICINE: THE PRODUCT OF THE REIGN.

WHEN, perhaps a century hence, the historian sets himself to write of preventive medicine, the reign of QUEEN VICTORIA will occupy a position of no mean degree in the pages of the work. The era has been remarkable in that within its limits preventive medicine has, as we have pointed out, been born. When our beloved QUEEN ascended the Throne in 1837 the pages of the statute book were, from the point of view of preventive medicine, with one exception, unwritten upon, and it is not a little significant that the exception referred to, the Quarantine Act of 1825, should on the eve of the Diamond Jubilee have been erased from the statutes as a vexatious measure no longer to be tolerated. The birth and growth of sanitary science—for preventive medicine can now be justly termed a science—have been in the main the resultant of the concurrent operation of three important factors. These are the development of what must, for the want of a better term, be called the spirit of humanity, which attaches year by year increasing value to human life and well-being; a better appreciation of the economic fact that health is wealth; and last, but in no sense least, an increased knowledge of the laws which govern the spread of infectious diseases—laws which, rightly apprehended, make for health and prolong life. To these three factors may, perhaps, be added a fourth—namely, a relative absence of the disturbing influences of war. It would be an attractive and congenial task to trace here, step by step and in chronological order, the progress which preventive medicine has made during the sixty years of HER MAJESTY'S reign, but we must content ourselves with a brief general survey, which shall form, as it were, a sort of roll-call of the masters in the science and of the works with which their names are and will be associated. In the very year of the QUEEN'S accession to the throne there came into operation an Act which provided for the registration of births, deaths, and marriages, and which formed the starting-point of those "statistical classics" with which the name of WILLIAM FARR will always be gratefully identified. It was, however, the late EDWIN CHADWICK who first entered the lists in the cause of public health, and it was his energetic and persistent efforts which were largely responsible for the memorable Health of Towns Commission and for the placing of the Public Health Act of 1848 upon the statutes, an Act which was quickly followed by others of sanitary import. In his labours CHADWICK was ably supported by such co-workers as SOUTHWOOD SMITH, SUTHERLAND, GUY, ARNOTT, and KAY, and although his reign was but brief the student of public health will always regard him and his coadjutors as the pioneers of the science.

In the year 1847 the city of Liverpool set an excellent example by appointing DUNCAN its first medical officer of health, and to the City of London belongs the honour of having secured in the following year the services of SIMON, who, in 1855, was appointed the medical adviser to the Central Health Authority, for which he laboured with such signal success for well-nigh twenty-one years.

SIR JOHN SIMON.

It may be interesting, too, to call to mind that amongst the first medical officers of health who were appointed and who helped to build up the public health service of this country were BALLARD, BUCHANAN, BRISTOWE, and BURDON SANDERSON; and it has been to the generalship of SIMON, SEATON, BUCHANAN, and now THORNE THORNE, that we are indebted for those highly valuable annual reports of the Medical Department of the Privy Council and of the Local Government Board which have added in so marked a degree to our knowledge of the natural history of infectious diseases and of administrative methods; while on the more philanthropic side of public health we must not neglect to make honourable mention of the work done by such men as SHAFTESBURY, B. W. RICHARDSON, and PEABODY, all of whom in an unofficial

Hosted by Google

capacity have in a sense pushed forward the work of CHADWICK.

To STEWART and WILLIAM JENNER this branch of science is especially indebted for the differentiation of typhus fever and enteric fever—a differentiation which has been followed by the almost complete elimination of typhus fever from the country and by an enormous reduction of enteric fever; and similarly to SNOW'S historical reports in connexion with the distribution of cholera we must trace our knowledge of the manner in which certain diseases are water-borne. To BUCHANAN we owe a better understanding of the laws which govern the spread and distribution of enteric fever, typhus fever, and phthisis; while W. H. POWER'S remarkable researches have taught us what a high infectivity small-pox possesses, and how that if we would clearly comprehend the laws of epidemiology we must have regard to diseases affecting animals as well as those that affect the human species—a doctrine which surely receives support from the general principles of biology. To THORNE THORNE and POWER we are indebted for much that is now common knowledge in reference to the natural history of diphtheria; and these two observers, together with SHIRLEY MURPHY, have shown us some of the effects of the aggregation of children in the confined spaces of our public elementary schools. BALLARD, who has but recently passed from our midst, has left us his exhaustive researches into the relation of infantile diarrhœa to the temperature of the earth, researches which are being confirmed every day by other observers, and which have opened up fields of investigation in connexion with the vitality and growth of micro-organisms in the soil. It was BALLARD, too, who provided us with what is now the standard work on offensive trades and on effluvium nuisances. As to small-pox we have heard not a little of late, but we must here recall the fact that the Vaccination Acts of 1840–1871 have been passed within the Victorian era, and that during that time EDWARD JENNER'S immortal, though at first empirical, discovery has not only saved thousands from disfigurement or an early grave, but has received its justification in the general preventive inoculation work of PASTEUR and others. In connexion, too, with vaccination we must mention with appreciation the labours of SIMON, SEATON and the Epidemiological Society; as also of BUCHANAN, MCVAIL, and BARRY; and we may, perhaps, express a hope that ere the Victorian era passes into history the blessings of general systematic revaccination may be added to those of primary vaccination. During later years the progress made in isolation hospital accommodation must be recorded, as also must the extension through the operations of compulsory notification of our knowledge of the distribution of infectious diseases. To KOCH, KLEIN, PARSONS, and others we owe a more precise conception of the thermal death point of micro-organisms and of the effect of chemical disinfectants upon such organisms, while PARSONS has taught us much of the natural history of influenza. The variations, cyclical and seasonal, of epidemic diseases is a subject upon which BUCHANAN, MITCHELL, RANSOME, T. W. THOMPSON, and WHITELEGGE have enlightened us; and NETTEN RADCLIFFE has made it easy for the student of Levantine plague and cholera to trace at the present time the progress of these two diseases in the past The influence of England has made itself felt in matters relative to quarantine in all parts of Europe, and, indeed, of the world, and for this the country is indebted to SIMON, BUCHANAN, and more recently to THORNE THORNE for his able and energetic advocacy of medical inspection as opposed to quarantine at the International Conferences, while in matters affecting the health of the army the names of PARKES and DE CHAUMONT will be remembered with pride by the Army Medical Staff in all parts of the empire Probably, however, the most remarkakle feature, in a public health sense, of this long reign has been the complete revolution of our ideas in respect of infectious diseases by the discoveries as to bacteria and their products, and in this connexion we are called upon to extol with France the genius of PASTEUR and with Germany the work of KOCH. The intensification and attenuation of disease viruses have been the event of recent years, and although the subject is still almost *in embryo* we may hope before long not only to add curative but protective inoculation to our victories over a variety of hitherto practically uncontrolled diseases. Amongst workers in England we recall the eminent services rendered throughout the world by the teachings of LISTER in connexion with antiseptic surgery, and the highly valuable work done by BURDON SANDERSON and KLEIN in the pathology of the infectious diseases. Amongst foreign bacteriologists there crowd in upon us such names as KLEBS, LÖFFLER, EBERTH, GAFFKY, JANOWSKI, BEHRING, KITASATO, DAVAINE, BOSSANO, BRIEGER, FRAENKEL, HAFFKINE, ROUX, YERSIN, and a host of others.

With the mention of these names we must close this necessarily imperfect sketch, but not without insisting upon the fact that the progress of sanitation in the English sense during the Victorian era has been by no means confined to these islands alone. As we have already pointed out, its influence has extended in certain directions all over Europe, but what is perhaps a matter of especial concern to us as Englishmen is that the mother country has sent out to that Greater Britain beyond the seas men like GRESSWELL to Australia, SIMPSON to Calcutta, and more recently GEORGE TURNER to the Cape, there to engraft the principles of English sanitation, and, while preventing in the colonies of the Empire the development of sanitary defects which age has to some extent inflicted upon us at home, to take advantage of the facilities which modern science affords for promoting and protecting the health of our descendants.

THE QUEEN'S REIGN AND THE MATERIAL AND SOCIAL POSITION OF THE MEDICAL PROFESSION.

THE last sixty years have seen great changes in the material and social position of our profession. The QUEEN'S own reminiscences and impressions of the distinguished men who have served her medically would be deeply interesting. Her appreciation of medical service has been always of the keenest and soundest order, and it would be strange indeed if in this just estimate of the profession she were not followed by public opinion. Yet there is a tendency in some minds to represent the public as less appreciative of the profession than it used to be, and the profession itself as less careful of its own methods and less worthy of the respect of the public than it was in former times. Some who hold this opinion might be ready to admit that the select few of the profession from whom HER MAJESTY'S advisers are taken are as worthy and exemplary as any of their predecessors, but would be disposed to maintain that in the rank and file there is a declension in scientific and intellectual standard in professional methods, in manners, and in social status. Such views can only be put forward out of utter and idle ignorance. The profession in point of numbers is probably twice what it was sixty years ago, so that there are twice as many persons to make a livelihood. It is true that the population of these islands has also increased, but the resulting situation is simply competition, and competition means hardship in individual cases, but it means improvement in general standard. In 1876 there were roughly 22,000 medical practitioners on the Register; there are now 34,000. A generation back BENJAMIN BRODIE spoke of the keen competition of the profession. How much more may we recognise it now?

Hosted by Google

Competition must be allowed for in passing judgment on the profession and its ways, and in trying to estimate its position in a social respect, compared with what it was sixty years ago.

It is easy to adduce any number of facts which go to support the view that in all essential respects the profession has grown in public usefulness and in public esteem. The very numbers of it are a testimony to such a rise. Men in a wealthy age and country do not flock into a declining profession as they have rushed of late into ours. Compared with the growth in influence of other professions, we have every reason to be satisfied with our own. Neither Divinity nor Law are enough to satisfy men now in respect of the great questions which exercise their minds. The evidence of medicine is sought. This may well be so when we consider the length of the medical curriculum and the field of study which has to be covered by those entering the profession. It is still more intelligible when we remember the enormous and rapid development of medicine and surgery during the sixty years which we are all commemorating, accomplished in large part by men in actual practice, and therefore in constant contact with human nature in all its varied moods and conditions. We do not contribute many members to Parliament, but in the constituencies which are responsible for sending members there are few more influential persons than the members of our own profession. They have not yet found out their full influence, and we are thankful to say that politics play no part in professional successes; but when questions of wide popular interest are on the *tapis* the medical vote and word are already of importance and are bound to become more so. The quiet influence of medical men in the municipal and local life of the country is difficult to realise. But that it is very extensive and beneficial is often strikingly illustrated in our columns by the short biographies of men whose names do not perchance appear in the medical journals until we have to record their deaths.

Medical societies have multiplied and grown in prosperity beyond all precedent. Not only in the capitals, but in almost every provincial town of any consequence medical societies exist, where men stimulate each other in the science and art of their profession by the comparison of methods and the interchange of ideas. But the success of these societies only serves to make more apparent the undoubted and regrettable facts that the organisation and the discipline of the profession are sadly incomplete. Almost within the years of HER MAJESTY'S reign a medical association has been established with half the profession in its membership, and this has attained to such a state of prosperity as can only be marred by the unfalthfulness of its best elements. Yet a spirit of general content with a condition which is undoubtedly one of progress is certainly not prevalent. In matters of ethics the profession can take care of itself. The great disciplinary influence of the profession is its own public opinion and the sound and subtle sense of what is honourable among its own members, and the best proof of the efficacy of these agents lies in the infrequency of gross cases of professional misconduct calling for the attention either of the law courts or of the General Medical Council or of the qualifying bodies. But in matters more concerning the worldly prosperity of the rank and file of the profession the leaders take little interest and the masses are divided in counsel. The profession is in some degree abused by the State, and is in no way protected by the State from gross exploitation, and these facts are known, while their remedy is not so obvious. This, however, is a little cloud in the brilliancy of medical affairs in the Victorian era upon which we do not desire to dwell at the present moment. Amid many grievances and disadvantages the profession bears itself with dignity, and establishes itself in the estimation of society and of those who best represent society. Within comparatively recent years leaders of the two great political parties have taken more than one opportunity of expressing their very high estimate of the position and prospects of medicine, while the State in its own interest has of late had to multiply its medical servants, until State medicine has become a special branch of study, fitting men for duties and offices altogether distinct from ordinary medical practice.

This steady and constant rise in the social status of the profession applies to all its branches. The leading medical men of the day hold their ground in any scientific society or in any social gathering. The House of Lords is more complete for having one medical Peer, but it will need several more before it does justice to itself or to the State. We may safely assume that the medical members of the Lower House are likely to increase. But the true rise of the profession is best seen in the fact that with an ever-increasing tendency to specialism the general practitioner stands out as the basis of the pyramid. He has risen and with him the profession has risen. There are those, we believe, who sigh for the old-fashioned apothecary, with his black clothes and his white cravat, and no doubt he was often an extremely respectable old gentleman, with his ready diagnosis and his equally ready medicaments for the few diseases in his nosology. But they must sigh in vain. For men of the type of Mr. PENDENNIS, senior, who "exercised the profession of apothecary and surgeon in the city of Bath, where he not only attended gentlemen in their sick rooms and ladies at the most interesting periods of their lives, but would condescend to sell a brown paper plaster to a farmer's wife across the counter or to vend tooth brushes and London perfumery," are obsolete. For many years they have been a vanishing quantity, and now they are lost to the social scheme, and, on a broad view of the question, it must be admitted that the public conception of medical practice has been raised thereby. The trade element in it is diminishing. Medical life is not an affair of nostrums and draughts and pills, but of intelligence and cultivation and capability. The apothecary has become the general practitioner, and the general practitioner is more and more perfecting his knowledge and his ability.

UNIVERSITY OF CAMBRIDGE.—At the congregation on June 10th the establishment of the new lectureship in Experimental Psychology was carried by 37 votes to 5. The degree of Doctor of Medicine was conferred on Walter Broadbent, M.A., B.C., Trinity; A. S. F. Grünbaum, M.A., B.C., Caius; J. C. Waithman, M.A., Magdalene; and A. L. Jackson, M.A., B.C., Clare. The degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on W. F. Lloyd, B.A., Clare; C. A. Robinson, B.A., Caius; A. P. Beddard, B.A., Trinity; W. Myers, B.A., Caius; and F. F. Ward, B.A., Selwyn. The degree of Bachelor of Surgery was also conferred on Dr. Waithman, Magdalene.

FOREIGN UNIVERSITY INTELLIGENCE.—*Atlanta Medical College:* Dr. Charles Minor Blackford has been appointed Lecturer on Pathology, Bacteriology, and Histology.—*Berlin:* Dr. G. Behrend, *privat-docent* of Dermatology, has been granted the title of Professor.—*Chicago Medical College:* Dr. Henry Gradle has been appointed Professor of Ophthalmology and Otology in succession to Dr. M. S. J. Jones, who has resigned.—*Halle:* Professor Fehling, who had been offered the chair of Midwifery at Tubingen, has decided to remain at Halle.—*Heidelberg:* Dr. Schottländer *privat-docent* of Midwifery has been promoted to an Extraordinary Professorship of that subject.—*Michigan (Ann Arbor University)*: Dr. Arneill has been appointed Assistant Professor of Medicine.—*Vienna:* Dr. Alfred Topolanski, of the ophthalmic department of the hospital connected with the sisters of charity, has been recognised as *privat-docent* in Ophthalmology in the University.

The Lancet Special Commission
ON THE
METROPOLITAN WATER-SUPPLY.

XV.[1]

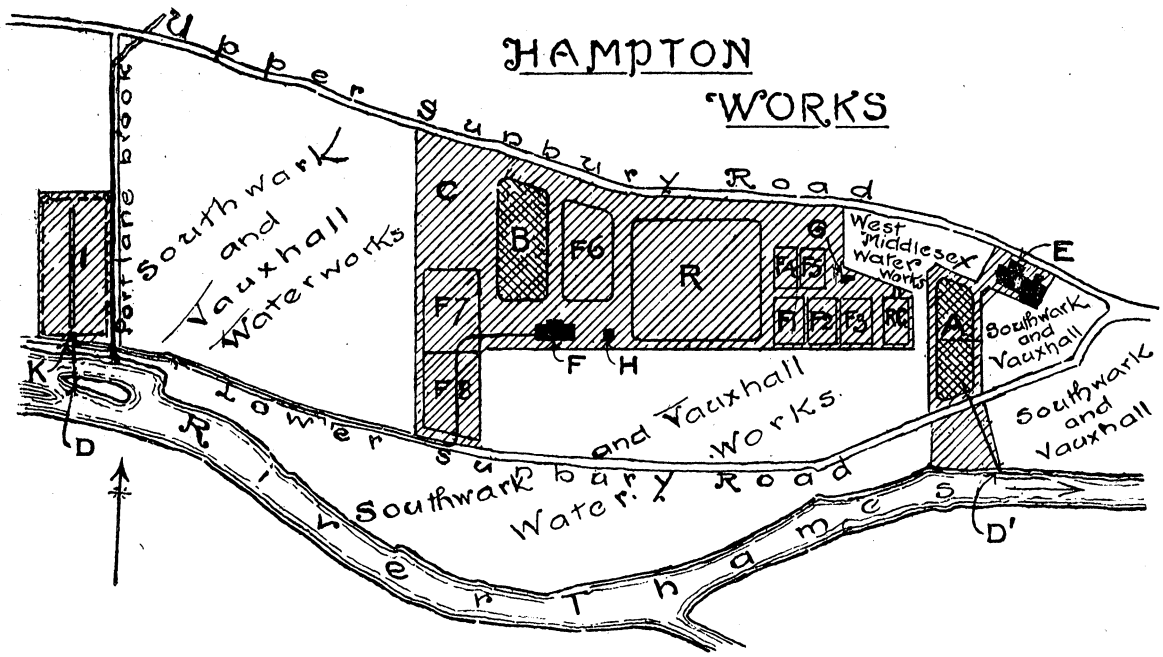
THE GRAND JUNCTION WATERWORKS COMPANY.

History.—In the year 1798 the Grand Junction Canal Company obtained an Act of Parliament (33 Geo. III., c. 33) to enable them to supply water to the inhabitants of Paddington and the places adjacent. The project was not, however, at once carried out. In November, 1810, an announcement was made in the newspapers that "works are now constructing and reservoirs making, under the direction of Mr. Rennie, the engineer, with powers to effect their purpose far superior to any other in the kingdom, and calculated to give to the inhabitants and streets supplied an abundance of pure and excellent soft water even in the upper stories of houses or other buildings." It was pointed out that the height above the Thames from which the water was to be taken enabled the proprietors to convey it at a very small expense to the parishes of Paddington, Marylebone, and St. George Hanover-square, and to the new streets which were then being built in these neighbourhoods. The advertisement went on to say that the "grand main at present casting" was 30 in. in diameter, and it was announced that a company would be started for carrying out the work as a business distinct from that of the Grand Junction Canal Company. A favourable account was given of the water which was to be supplied, and it was said to be "excellent for all culinary and domestic purposes." "It is also," the prospectus went on to say, "lighter and contains less foreign matter than the Thames water." It was added that additional reservoirs were being made, and streams of water "of the finest quality" were being used, and that there would be a sufficient supply for 40,000 houses. It was obvious, the advertisement stated, that the undertaking would be attended with great public benefit, and the proprietors trusted that they had "reason to feel confident of the liberal support of the public." The Company for carrying out the new undertaking was formed under an Act of Parliament passed in the year 1811 (51 Geo. III., c. 1, 69). The expense of carrying out the undertaking proved to be considerably more than was expected, and the Company at first experienced considerable difficulties with regard to raising new capital when it became necessary to do so. A great deal of money was lost because the Company at first adopted the use of stone pipes, which were recommended by Mr. Rennie. It was soon found that these were very unsuitable for the purpose, and it became necessary to substitute iron pipes. At first the Company obtained their water from the Grand Junction Canal, which in its turn was supplied by the River Colne and River Brent. Water was also obtained from a reservoir of nearly 100 acres, which was filled by streams of the Vale of Ruislip. It was said that these sources were remarkably pure and that the water was superior both in softness and transparency to that derived from the Thames. Experience, however, proved that the water was not by any means perfect, and the directors acknowledged that the quality of the water taken from the canal "had disappointed the expectations of the projectors of the original plan," for it was found to be impossible to keep the land drainage out of the canal, and the Ruislip Reservoir. It was discovered also that the waters of Brent were "so foul that it was necessary to prevent their entering the canal," and a like necessity caused the waters of the Ruislip Reservoir to be conducted by a tunnel under the canal. The supply from both these sources proved unfit for the use of the waterworks. In consequence of this arrangements were made for obtaining water from the Regent's Canal Company, but the supply proved inadequate, and complaints were made both as to the quantity and quality supplied to the customers. The Company at length decided to obtain water from the Thames, and about four acres of land were bought at Chelsea. The site chosen was between the Royal Naval Hospital and the Chelsea Waterworks. The water was obtained through a conduit pipe laid into the bed of the river and was pumped by steam-engines to the station at Paddington, a portion of the site of which is now occupied by Talbot-square and Norfolk-square. There were three reservoirs at Paddington capable of holding 153,000, 139,000, and 65,000 hogsheads respectively. Thames water was allowed to remain for some time to settle before it was pumped for the supply of the customers. The higher parts of the districts were supplied by pumping from Paddington over a standpipe 61 ft. higher than the reservoir, which was 85 ft. above the Thames high-water mark. For the low-service supply the water flowed directly from the reservoirs. In the year 1830 the district supplied was chiefly Paddington and the part between Oxford-street on the north and the Green Park on the south. In the year 1831 the directors of the Company adopted a rather ambitious scheme for supplying the whole of the metropolis with water. It was proposed to supply Middlesex, Surrey, and part of Buckinghamshire, and the scheme included deepening and embanking some miles of the River Colne from its entrance into the Thames near Staines. Water was to be conducted through a canal 27 ft. in width and 4 ft. 6 in. in depth and was to have two footpaths, one on each side. The work would have been one of considerable magnitude. The conduit was to pass over no less than twenty-six rivers, streams, and sewers, over thirty roads, lanes, and footpaths, and one of the aqueducts, it was said, would have been about three times the length of Blackfriars Bridge. There were also to be two tunnels, each 1000 ft in length. The Bill for carrying out the project was referred to a committee of the House of Commons in April, 1831, and it was not passed. In the year 1835 the Company was authorised to remove their intake from the Thames at Chelsea to Brentford, just above Kew Bridge. In 1852 an Act was passed compelling the metropolitan water companies to take their supply from some part above the tidal river, and an Act was therefore obtained to enable the Company to remove their station to Sunbury.

Present state: general description.—The Grand Junction Waterworks Company supplies Sunbury, Hampton, Teddington, Hounslow, Sutton, Isleworth, Brentford, Hanwell, Ealing, Acton, Shepherd's Bush, Notting-hill, part of Bayswater, Paddington, Hyde Park, and Mayfair. The water is derived chiefly from the Thames at Hampton, but a small quantity is obtained from the gravel beds there. The Company's stations are—Hampton intake, arrangement for taking water from the gravel bed, reservoirs, filter beds, pumping station; Kew Bridge, Brentford, reservoirs, filter beds, and pumping station; Hanger-hill, Ealing, reservoirs, pumping station; Campden-hill, reservoirs, pumping station.

Hampton (see Fig. 1).—The Hampton station is situated in the parishes of Hampton and Sunbury, Middlesex, between the upper Sunbury-road and the Thames. Several alterations are in progress here. As in the case of the Southwark and Vauxhall Waterworks, a map is given showing the part of the station in which changes are going on, and it may be best to briefly describe the general arrangements of the station before going into detail. At the eastern extremity of the works there is an engine-house marked E on the plan, and next to this the part cross shaded, marked A, is an old reservoir which is now in progress of conversion into filter beds; further to the west is a covered reservoir, R C; five filter beds, marked F 1 to 5; and a small engine-house G. Still further to the west there is a reservoir R; beyond this another engine-house, having to the north of it a preliminary filter bed, F 6. At the part marked B another preliminary filter is being converted into two beds of the ordinary type. F 7 and F 8 are preliminary filters. The land immediately to the west of these belongs to the Southwark and Vauxhall Company,[2] and beyond this, in the part marked I, there is an arrangement for filtering river water through gravel beds. Immediately to the south of this on the island is the new intake of the Company; DD shows the old intake. With regard to the pumping arrangements, it may for the sake of clearness be best to say in this place that the work to be done is of three kinds. Firstly, water has to be pumped from the river to the filter-beds. Secondly,

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., and XIV. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, respectively.



[2] It is the part marked E, Fig. 1, THE LANCET, March 20th, 1897, Article V.

Hosted by Google

water after filtration here is pumped directly for the country district. Thirdly, water is pumped to Kew Bridge, where it is filtered for the supply of the London district. Roughly speaking, the amount of the local supply is 6,000,000 gallons, and the amount pumped to Kew Bridge is 14,000,000 gallons daily.

Intakes.—The chief intake of the Company is from the Thames, and is situated on a small island which is separated from the Middlesex shore by a backwater about 20 yards in width. At the part of the bank at which the water is taken there is a bay about 40 ft. across, and the intake is protected mean summer level. The water thus collected from the ballast on the island, the water taken from the Thames, and the water collected from the foreshore in the pipes just described is conducted through a 30-in. pipe to an engine-house H. A certain amount of water is also obtained by a special arrangement situated in a meadow marked I just to the north of the Lower Sunbury-road, and this water passes with that derived from the sources just mentioned. The old intake marked D is situated between those of the Southwark and Vauxhall and the West Middlesex Companies, and from this source water is taken for the supply of the filter beds.

by a floating boom. There are four gratings formed of bars, which are placed about 3 in. apart, and the depth of the gratings is 2 ft. 6 in. These are cleared as occasion requires. In the autumn, when the river contains a large number of dead leaves, it is found necessary to keep a man constantly at work at it, but at other times the boom keeps off most of the débris. Through the gratings the water flows into a chamber, of which the walls are some feet above the highest flood level, so that it is possible to go there whatever the state of the river may be. The height of the walls of the chamber is 11 ft. above the mean summer level of the river, its size is 24 ft. by 6ft., and there is a grating at the top. Into the chamber situated to the west the water passes through three 30-in. sluices, and after going through the chamber it is continued across the backwater in two 30-in. pipes. On the foreshore there is an inspection chamber (Fig. 1, K.), 6 ft. by 18ft inside measurement. The water is received into this, and is then conducted to the engine-house (F) by two 36-in. pipes. A second intake from the Thames on the island conducts the water into a smaller reception chamber, which is situated on the eastern side, and adjoining the one just described. The chamber is separated from the other by a brick wall. On the island three layers of open jointed pipes were placed to receive water from the layer of ballast which is situated there. The line of pipes is about 8 ft. below the mean summer level of the river. Two of these lines of pipes are still in working order, but it is found that very little water is collected by them except in flood time. The water thus collected passes into the chamber with that taken from the river, and is then conducted to the main land across the backwater through a 30-in. pipe. On the foreshore there is another arrangement for collecting water from the ballast. A line about 50 yards in length of 24-in. pipes is laid with open joints at a depth of about 8 ft. below the

Gravel water system. — From the foreshore inspection chamber which has been described a 24-in. iron pipe conveys the water for a distance of about 40 yards to the meadow, passing in its course under the Lower Sunbury-road and conducting it into a filter screen. The filter screen is an arrangement of unusual character. A trench (see Fig. 2) 12 ft. in depth and 60 yards in length was dug in the meadow; the lower part of the trench is 6 ft. in width, and the upper part 10 ft.; the sides are concreted to a depth of about 15 ft. from the surface, but the lowest part is perforated by small drainage-pipes. The bottom of the trench is filled with washed and screened ballast and fine shingle to a depth of 3 ft. The

FIG. 2.

The trench in section.

FIG. 3.

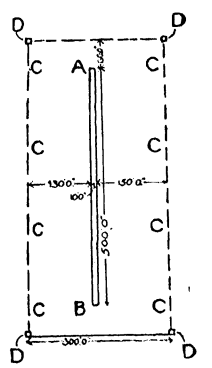

Diagram of section of filter screen.

Hosted by Google

water flows in by gravitation from the inspection chamber, and its height is regulated by a cock. As a rule it is kept at about 1 ft. below that of the mean summer level of the river, and as the surface of the filter screens is 2 ft. below this the depth of water above the screen is of course about 1 ft. The water which covers the filter screen gradually percolates through the filter screen and then into the ballast which is situated in the meadow, and after passing for about 150 ft. or so through this natural filter it is collected by a layer of pipes which were laid in the ballast for that purpose. This series of collecting pipes surrounds the filter trench (see Fig. 3 c c). The pipes are situated 12 ft. below the mean summer level; they are of earthenware, 24 in. in diameter, and are laid with open joints. They conduct the water to two brick shafts (see Fig. 3 B) which are in a line with the 30 in. main, and the water passes from them into this main. The surface of the filter screen is cleaned in the same way as that of an ordinary filter—that is to say, the surface is skimmed off to a depth of about 1 in. every month or so.

Pumping arrangements.—The water passes by gravitation through the two 36-in. pipes previously described to an engine-house called the Reidler House, marked F on the map. It is pumped thence either to the reservoir (see Fig. 1, R) or to the preliminary filter-beds (see Fig. 1, F, 6, 7, 8).

Engine-house.—The engine-house contains two pairs of Reidler engines, one pair high lift and the other low lift, a centrifugal and Worthington engine. The low-lift Reidler engines pump the water into the reservoir R and into the preliminary filter-beds, F 6, 7, 8. The centrifugal engine is used for the same purpose. The high-lift Reidler engines pump the water from the preliminary filters and from the reservoir to Kew Bridge. The Worthington engine is used for the same purpose.

Low-lift Reidler engine.—This engine has cylinders of 11 in. and 20 in. and a stroke of 27 in. It works double-action plunger pumps, the cylinders of which have a diameter of 23 in. It therefore lifts 165 gallons per stroke and it is worked at the rate of sixty revolutions a minute.

High-lift Reidler engine.—This engine has cylinders with diameters of 21 in. and 39 in. and a stroke of 36 in. The diameter of the pump cylinder is 20 in. It is worked at a rate of sixty revolutions per minute.

The Worthington engine has cylinders 9½ in., 14 in., and 25 in., and a stroke of 2 ft. 3 in. It works a plunger pump which has a cylinder 30 in. in diameter. It pumps 48 gallons per stroke, and the number of revolutions is from 45 to 50. These engines are worked by seven Lancashire boilers at a pressure of 90 lb. The head of water worked against in pumping to the reservoir is 28 ft., and in pumping to Kew 130 ft.

Horizontal engine-house.—This house contains two horizontal engines having cylinders of from 16 in. to 21 in. in diameter respectively. These work three-throw pumps, which raise the water brought from the river and the gravel-beds through the 30-in. pipe, and raise it to the reservoir and to the filters which are used for the local supply. The pumping capacity is 11,000,000 gallons per day, but about 4,000,000 gallons only are usually required.

Filters.—Preliminary filter, F 6. This has an area of three acres, and it is surrounded by a puddle wall taken down to the London clay. The filtering material consists of 2 ft. of sand and 4 ft. of screened ballast. The filtered water is collected by three 24-in. earthenware pipes which conduct it to the Reidler engine-house. There are no cross drains.

Preliminary filter beds (F 7 and 8).—There are two beds called "preliminary" filter beds, each of which has an area of about one and three-quarter acres. The upper parts are lined with blue Staffordshire bricks, the upper 2 ft. of the walls are vertical, and the lower part is formed of concrete at a slope of two and a half to one. The bed of the filter is formed as follows: Sand 2 ft. 6 in., ballast 1 ft. 6 in. to 2 ft. The ballast is thicker at the centre than at the sides of the bed, and the floor slopes gradually towards the centre, where it is 6 in. deeper than it is at the sides. When cleansed the sand is reduced in thickness from 2 ft. 6 in. to 2 ft. The filtered water is collected in earthenware pipes 12 in. in diameter, which are laid with open joints and conduct the water into a central culvert.

Storage reservoir (See Fig. 1 R).—This reservoir covers an area of about ten acres, the upper part is lined with blue Staffordshire bricks, and the walls, which are built of concrete, have a slope of 3 to 1. It is surrounded by a puddle trench, which goes down to the London clay. The reservoir is 22 ft. deep, and is said to be capable of storing 45,000,000 gallons of water. The water for the supply of this reservoir comes from the river in part through a 36-in. main, and gravel water is also pumped here.

Water for the London district is pumped from Hampton to Kew and filtered there; for the local supply the water is filtered at Hampton and distributed directly to the district.

Filter beds.—The five filter beds which are used for the local supply (see Fig. 1, F 1 to F 5) have an area of three-quarters of an acre each. They are of oblong form; the upper part is lined with Staffordshire bricks. The walls of No. 4 and No. 5 are nearly vertical. The filtering material is formed of 2 ft. 6 in. of sand and 2 ft. of shingle. For the collection of the filtered water there is a central culvert, of which the sides are built in part with perforated bricks to allow the passage into it of the filtered water. The upper part of the culvert has stone covers. Water is conducted to its perforated sides through land drain pipes 2 in. in diameter. These filter beds have no ventilators. The sides of beds Nos. 1, 2, and 3 have a slope of 2 to 1. In other respects they are similar to filters 4 and 5.

Cleansing filter beds.—As a rule filter beds are cleansed once a month and in early spring more frequently. The sand is always washed by means of an apparatus made of cast iron hoppers with ejectors. The pressure of the water used is about 150 ft. It is found that 4500 gallons of water are used in washing a cubic yard of sand. When the sand was washed by means of high pressure without this hopper arrangement no less than 7000 gallons of water were used in washing a cubic yard. The sand is very efficiently washed by the arrangement in use at this station.

The rate of filtration.—The maximum rate of filtration is 2½ gallons per square foot per hour. As a rule the rate is 1⅞ gallons per square foot per hour.

Pumping arrangements for the country district.—For the local supply of water a diagonal engine situated in a house marked G and two pairs of beam engines are used. The diagonal engine is one of unusual form—is capable of pumping 176 gallons per stroke and works at a rate of 14 per minute. The steam for working the engine is generated by three Lancashire boilers, and the pressure used is 80 lb.

Covered reservoir.—There is a reservoir covered by concrete arches built on steel girders which are supported by brick piles. This reservoir is capable of storing 3,000,000 gallons. The water from it is used entirely for the local supply. It passes to the engine-house (marked E) and is pumped by the beam engines.

Engine-house (E on map).—The western part of the engine-house contains two beam engines, which have cylinders 24 in. and 48 in. in diameter, and a stroke of 8 ft. This works bucket and plunger pumps; the diameter of the bucket is 29½ in. and that of the plunger 21 in. The steam pressure used is 60 lb. The head of water worked against is 150 ft. The pump discharges 236 gallons per stroke and the rate is about 12 per minute. There is an electrical communication between this house and Hampton Court Palace. The Company have arranged to supply water there in case of fire. The engine is worked by four Lancashire boilers at a pressure of 60 lb.

Bull engines.—There are three direct acting Cornish engines of the Bull type. Of these one has cylinders of 70 in. in diameter, and two have cylinders of 68 in. These engines were formerly constantly used for pumping water to Kew, but they have not been much used since the erection of the Reidler engines in 1891. Of these engines two are capable of pumping 559 gallons per stroke, and were worked at a rate of about twelve a minute, and the other is capable of pumping 695 gallons per stroke, and was worked at a rate of about eleven strokes per minute. The steam for these engines was supplied by four Cornish boilers at a pressure of 40 lb.

The course of mains from Hampton to Brentford.—A single 33-in. main conveys the water through Twickenham and Isleworth. The course of the main is along the high road. From Isleworth—that is to say, for the last two miles—the water is conducted in two 33-in. mains.

(To be continued.)

THE Chinese Government has conferred on Mr. David Craigil Gray, M.B., C.M. Glasg., the Order of the Double Dragon in recognition of services rendered to the Chinese wounded during the late war with Japan. This Order entitles him to the rank of a Third Button mandarin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 10th, the President, Sir WILLIAM MACCORMAC, being in the chair.

Sir James Paget, F.R.S., and Lord Lister, P.R.S., were introduced, and the President presented to each the honorary medal of the College, with a document declaratory of the award thereof.

Mr. Charles Sissmore Tomes, F.R.S., was introduced, and the President handed him a cheque for the amount of the John Tomes Prize, with a document declaratory of the award.

In accordance with the recommendation of the Board of Examiners in Dental Surgery, the Council added the Sheffield Royal Hospital to the list of hospitals the dental departments of which are recognised for dental hospital practice.

The Library Committee were directed to advertise the vacancy in the office of librarian, to consider the applications, and to nominate a candidate to the Council for election.

A report from the Laboratories Committee was adopted; it was as follows:—

"1. *The work on Diphtheria for the Metropolitan Asylums Board.*—The Preparation of Antitoxin Serum. Since March 5th the director has supplied 3125 doses of antitoxic serum containing 4000 units each, 944 doses containing 3000 units each, and 50 doses containing 1000 units, for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, and all the demands have been fully met. During this period 15,382,000 units have been supplied, against 14,028,000 units last quarter, being an increase of 1,354,000 units.

"2. *Researches in connexion with the Grant from the Goldsmiths' Company.*—Dr. Cartwright Wood and Dr. T. G. Brodie have continued their investigations, but as yet have nothing further to report. In fulfilment of one of the conditions of the grant from the Goldsmiths' Company, that antitoxin should be, if possible, supplied for use amongst the poorer classes of the community, antitoxic serum has continued to be supplied to various general and children's hospitals in London during the past quarter, as well as to certain medical practitioners for cases fulfilling the necessary conditions."

The Council proceeded to appoint the following examiners for the ensuing year:—Elementary Biology: J. B. P. Beale, George A. Buckmaster, Thomas W. Shore, and Thomas G. Stevens. Anatomy under the Conjoint Board: Stanley Boyd, W. Bruce Clarke, George H. Makins, and Arthur Robinson. Physiology under the Conjoint Board: John R. Bradford, Leonard E. Hill, and Walter G. Spencer. Anatomy for the Fellowship: William F. Haslam, Walter H. A. Jacobson, Charles B. Lockwood, and John Bland Sutton. Physiology for the Fellowship: Thomas G. Brodie, D'Arcy Power, Ernest H. Starling, and William H. Thompson. Midwifery under the Conjoint Board: Montagu Handfield-Jones, Arthur H. N. Lewers, Amand Routh, and Herbert R. Spencer. Public Health: Part I., Arthur P. Luff; Part II., Edward Seaton.

The committee which had been appointed to consider a memorial signed by forty-one members of the medical profession resident in Norwich, asking for the advice and guidance of the Council on the question of meeting in consultation the medical officers of the Norwich Medical Institute, and which had also received a deputation from the medical profession in Norwich, presented a report, and it was resolved that—

"The Council, having considered the memorial of members of the medical profession in Norwich and the additional statements made by the deputation from Norwich, are of opinion that the disciplinary powers provided by Section XVI. of the by-laws do not entitle the Council to call in question the legality of Fellows and Members of the College holding the appointment of medical officer to the Norwich Medical Institute or to similar institutions, and therefore they cannot endorse the refusal of any of its Fellows and Members to meet in consultation (particularly in urgent cases) registered practitioners when acting in conformity with their legal rights."

In reply to a letter from Dr. Frederick Pearse, the honorary secretary of the Portsmouth Medical Union, asking whether the College were prepared to take action against its Members for employing men to "tout" and canvass from door to door for them, the following reply was directed to be sent:—

"The Council, while not prepared to express an abstract opinion on the question raised by the Portsmouth Medical Union, are willing to consider any evidence which may be submitted to them respecting canvassing for patients either directly or indirectly by any individual Fellow or Member of the College with a view to determining whether or not such Fellow or Member has been guilty of a breach of the by-laws."

A letter was read from Mr. J. H. Square May pointing out that the reply of the Council to the memorial from Members and Fellows of the College in Plymouth on behalf of Mr. R. B. Anderson does not allude to the request that the Council should explain why Mr. Anderson's case does not come under By-law XV., and asking for an explanation on this point. The Council resolved: "That Mr. May be informed that the Council do not consider it is incumbent upon them to give explanations of the conclusions at which they may arrive, but are of opinion that Mr. Anderson's case does not come within the terms of Section XV. of the by-laws." A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at their late session. The best thanks of the Council were voted to Mr. Bryant for his services as the representative of the College on the General Medical Council.

The candidates for the vacant places on the Council of the Royal College of Surgeons of England are:—

	Member.	Fellow.
Howse, Henry Greenway	1865	1868
Cousins, John Ward	1856	1860
Owen, Edmund Blackett	1868	1872
Godlee, Rickman John	1872	1876
Cheyne, William Watson	1879	1879
Lucas, Richard Clement	1868	1871
Morgan, John Hammond	1872	1876
Dalby, William Bartlett	1867	1870
Jackson, George...	1864	1876
May, Bennett	1868	1876
Clark, Andrew	1869	1873

There are five vacancies. Mr. Howse and Dr. Ward Cousins seek re-election.

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND LORD LISTER.

THE following letter to Lord Lister has been enclosed to us for publication by Mr. George Jackson and Mr. R. B. Anderson, with a note to the effect that "did time permit the letter would be numerously and influentially signed, but the importance and correctness of the principles submitted will not," the writers trust, "depend in Lord Lister's estimation on those who thus inadequately represent them."

[ENCLOSURE.]

10, Portland-villas, Plymouth, May 10th, 1897.

To the Lord Lister, F.R.C.S. Eng., &c., &c., &c.

YOUR LORDSHIP,—As the Fellows' Association will not take action on the occasion of the approaching election of members of Council of the College of Surgeons, the Society of Members of the College is desirous of obtaining the support of independent candidates and electors to the claims of the Members for a reform of the College—e.g., (1) for a moderate representation of the Members on the College Council; (2) for the right to assist in electing the President of the College; (3) for the fulfilment of its undertaking given by the Council in Section XV. of the by-laws to "protect and defend" "Fellows and Members" who "may be disturbed" in the exercise "of rights acquired by them as Fellows and Members" or as "Members"; and (4) for the right to assist in choosing the representative of the College on the General Medical Council.

These measures have, to a greater or less extent, been advocated amongst the Fellows up to this period; and some have been received with favour. We believe a large proportion of the five hundred Fellows who on the issues as hitherto unfavourably and inadequately set before them have not voted would support a definite policy of reform, to be carried with spirit to an early issue, besides two hundred who have voted for a moderate extension of the franchise to the Members. Should it be found that the Fellows, as a body, reject the just claims of the Members, the latter contemplate moving in Parliament for an Act to reform the corporation. In case your views are in favour of such a policy of justice and conciliation towards those who are the corporation, and of whom, though Fellows, we ourselves are units, we venture to invite you on behalf of reform, though without asking you for any present expression on the subject, to permit yourself to be placed in nomination for the approaching election to the College Council. You would then be in the best position as the movement advances to aid it by your great influence in such respects as you may deem wise and salutary.

We have the honour to be, your Lordship's most obedient servants,

C. B. KEETLEY, R. B. ANDERSON,
GEO. JACKSON, SYDNEY JONES.

ANNUAL DINNER OF THE ARMY MEDICAL STAFF.

THE annual dinner of the Army Medical Staff was held on Monday last at the Whitehall Rooms of the Hôtel Métropole. The meeting was in every respect a pleasant one, and, as has been the custom in late years, there was no post-prandial oratory, the only toast given being that of the Health of Her Majesty the Queen. We may note that among some communications read by the Chairman was one expressive of good wishes from medical officers serving at Canea. The following are the names of the officers and their guests:—Surgeon-Major-Generals: Director General J. Jameson (in chair), A. F. Bradshaw, C.B., C.M.McD. Cuffe, C.B., Sir J. Fayrer, K.C.S.I., G. L. Hinde, C.B., J. Inkson, W. Nash, T. F. O'Dwyer, A. F. Preston, J. B. C. Reade, C.B., W. Taylor, W. M. Webb, and J. Warren. Surgeon-Colonels: O. Codrington, H. Cayley, W. G. Don, H. C. Herbert, C. H. Harvey, J. H. Hughes, J. H. Jeffcoat, C. M. Jessop, T. Ligertwood, J. Maturin, J. L. Notter, T. O'Farrell, W. Sly, and J. Watts. Brigade-Surgeon-Lieutenant-Colonels: W. B. Allin, B. M. Blennerhassett, C.M.G., J. F. Beattie, J. A. Clery, R. de la C. Corbett, W. Donovan, W. J. Fawcett, T. J. Gallwey, C.B., W. L. Gubbins, L. A. Irving, W. Keir, C. Mackinnon, H. Mackinnon, D.S.O., W. McNalty, A. A. Macrobin and W. Temple, V.C. Surgeon-Lieutenant-Colonels: J. A. Anderson, F. E. Barrow, U. J. Bourke, W. C. Chester, A. Doig, J. B. Emerson, J. Hector, G. A. Hughes, J. G. Leask, G. H. Le Mottée, R. H. Quill, A. B. Robinson, and T. Wright. Surgeon-Majors: F. M. Baker, J. Battersby, W. G. Bedford, A. E. J. Croly, A. Dodd, J. R. Dodd, H. Grier, F. A. Harris, J. L. Hall, J. G. Harwood, R. J. Hackett, H. E. R. James, R. Jennings, S. F. Lougheed, R. E. R. Morse, W. G. Macpherson, H. W. Murray, F. B. Maclean, C. G. D. Mosse, F. P. Nichols, E. North, R. Porter, G. W. Robinson, G. H. Sylvester, J. Tidbury, G. Wilson, and T. P. Woodhouse. Surgeon-Captains: C. H. Hale, D.S.O., H. St. G. Hore, E. M. Hassard, O. R. Julian, J. C. Jameson, R. E. Kelly, W. B. Leishman, F. J. Morgan, J. A. O. McCarthy, J. Paterson, O. L. Robinson, R. J. Windle. Captain and Quartermaster: D. J. Gillman.

The following guests were present: The President of the Royal College of Surgeons of England (Sir W. MacCormac), the President of the Indian Medical Board (Surgeon-Major-General Hooper), Surgeon-Major W. Collingridge, Militia Medical Staff Corps, Mr. Vesey Holt, and Mr. Thomas Wakley, Jun.

THE ROYAL SOCIETY CONVERSAZIONE.

"LADIES' NIGHT" at the Royal Society is, as a rule, made more attractive than the first exhibition of the year, and the demonstration and reception held on Wednesday last proved to be no exception to this rule. Pure science yields to some extent to popular science. Fittingly enough the visitors were met with a unique design in the entrance hall consisting of the words "Vivat Victoria Regina" displayed in a beautiful series of argon and helion tubes. Of course, Professor Ramsay was responsible for this beautiful display. It illustrated a pretty application of the properties of two important elements discovered only recently in this remarkable Victorian period. Perhaps the most fascinating subject of demonstration was that for which Messrs. Preece and Marconi were jointly responsible. At this exhibit was demonstrated with remarkable success the possibility of transmitting intelligence by means of electric waves, without the ordinary channel of wires, but simply with the ætheriferous medium which pervades all space. In the method shown electrical vibrations are set up by an electrical machine like an ordinary induction coil, which are caught up by a receiver some distance away. In thus bombarding the receiver, a bell is made to ring, and by the varying frequency of the ringing a message may be deciphered. The electric waves produced vibrate at the rate of at least 250,000,000 beats per second. The vibrations, indeed, are so rapid as to permeate rapidly through opaque substances, as, for instance, through brick walls. This fact promises to introduce possibilities of far more reaching consequence than even the x rays. It was further demonstrated that there might exist sufficient electrical disturbance in the muscles of the human body to actuate the instrument. Will this wonderful result afford a working basis for telepathy? By the method described communication was established between the islands and the mainland in the Bristol Channel, but at the Royal Society's rooms the demonstration was limited to an intervening space of some thirty feet. It was none the less convincing of a probable practical success in the future. Some experiments of extreme interest, and illustrating further developments in cathode rays, were shown by Mr. A. A. C. Swinton, Professor Silvanus P. Thompson, and Dr. Macintyre. The last-named gentleman exhibited a series of x ray kinematographic films showing in a beautiful and interesting manner the movements of the joints and sockets in a frog. A pretty effect was produced by Lord Kelvin in illustrating the production of electric conduction through air under the influence of uranium. Uranium salts have the peculiar and apparently inexhaustible property, too, of emitting rays of a similar character and frequency to the x rays, and analogous photographic effects may thus be produced. As to the rest of the exhibits they were, speaking generally, a repetition of the former exhibition, an account of which was published in THE LANCET of May 22nd. Thus examples of the recent advances in colour photography were shown, and the remarkable phenomenon of "commensalism" occurring amongst marine animals was again illustrated by the Marine Biological Association, whilst the pretty optical experiments exhibited by Mr. Shelford Bidwell and Mr. C. P. Butler were once more in evidence.

The President, Lord Lister, received the lady visitors and the Fellows, the company being a very large one, and including, as might have been anticipated, several distinguished persons who are present in England to attend the Diamond Jubilee.

THE PRINCE OF WALES'S HOSPITAL FUND: SOUVENIR OF THE QUEEN'S COMMEMORATION.

THERE will be many souvenirs, which will hand down to posterity the remembrance of this *annus mirabilis* of the British Empire, but among the most interesting of the records of the commemoration pageant will assuredly be that which was issued yesterday (Thursday), by the proprietors of the *Graphic* and *Daily Graphic*, under the auspices of the Prince of Wales's Hospital Fund and by authority of the Prince himself. We refer to the illustrated programme of the Royal Jubilee procession, the publication of which we have already advocated. The book is excellently got up and authentic in detail, as those in authority, knowing the object to which the results of all sales would be devoted and the interest Her Majesty takes in that object, have given the artists all possible facilities. We consider that the possession of this illustrated guide to Tuesday's pageant is almost a necessity to those who desire to understand the significance of the gorgeousness which will fill their eyes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5492 births and 3297 deaths were registered during the week ending June 12th. The annual rate of mortality in these towns, which had been 16·6 and 17·4 per 1000 in the two preceding weeks, declined again last week to 15·6. In London the rate was 13 8 per 1000, while it averaged 16 9 in the thirty-two provincial towns. The lowest death-rates in these towns were 8 2 in Croydon, 10·7 in Brighton, 12·0 in Swansea, and 12·3 in Huddersfield and in Plymouth; the highest rates were 20·3 in Manchester, 20·6 in Bolton and in Gateshead, 21·1 in Liverpool, and 23·7 in Salford. The 3297 deaths in these towns included 379 which were referred to the principal zymotic diseases, against 355 and 364 in

Hosted by Google

the two preceding weeks; of these, 131 resulted from measles, 90 from whooping-cough, 57 from diphtheria, 48 from diarrhœa, 28 from scarlet fever, 24 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was recorded last week in Plymouth or in Derby; in the other towns they caused the lowest death-rates in Croydon and Bristol, and the highest rates in Liverpool, Bolton, Sunderland, Burnley, and Salford. The greatest mortality from measles occurred in Manchester, Burnley, Birkenhead, Bolton, and Salford; and from whooping-cough in Burnley, Liverpool, and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 39 in London, 3 in Birmingham, and 3 in Sheffield. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns. There were 2 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, June 12th, against 13, 12, and 4 at the end of the three preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2637, against numbers increasing from 2380 to 2601 on the six preceding Saturdays; 255 new cases were admitted during the week, against 311, 278, and 274 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 196 and 229 in the two preceding weeks, declined again last week to 191, and were 60 below the corrected average. The causes of 45, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 22·3 to 20·3 per 1000, was again 20 3 during the week ending June 12th, and exceeded by 4·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·7 in Aberdeen and 16·1 in Greenock to 24·9 in Leith and 26·3 in Edinburgh. The 606 deaths in these towns included 37 which were referred to whooping-cough, 27 to measles, 15 to diarrhœa, 8 to "fever," 4 to scarlet fever, 2 to diphtheria, and 1 to small-pox. In all, 94 deaths resulted from these principal zymotic diseases, against 91 and 93 in the two preceding weeks. These 94 deaths were equal to an annual rate of 3·2 per 1000, which was 1·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 34 and 40 in the two preceding weeks, declined again to 37 last week, and included 14 in Glasgow, 10 in Edinburgh, and 9 in Leith. The deaths from measles, which had been 24 and 30 in the two preceding weeks, were 27 last week, of which 15 occurred in Edinburgh, 7 in Glasgow, and 4 in Leith. The 8 deaths referred to different forms of "fever" considerably exceeded the number recorded in any recent week, and included 6 in Glasgow and 2 in Dundee. The fatal cases of scarlet fever, which had declined from 6 to 2 in the four preceding weeks, rose again to 4 last week, of which 3 occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 128 and 110 in the two preceding weeks, further declined to 108 last week, but exceeded by 15 the number in the corresponding week of last year. The causes of 39, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3 and 25·2 per 1000 in the two preceding weeks, further declined to 22·4 during the week ending June 12th. During the past ten weeks of the current quarter the death-rate in the city has averaged 29·3 per 1000, the rate during the same period being 15·9 in London and 26·3 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed a decline of 19 from the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 15 and 10 in the two preceding weeks; of these, 4 resulted from scarlet fever, 4 from whooping-cough, 2 from measles, 2 from "fever," 1 from diphtheria, and 1 from diarrhœa. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 1·5 in London and 5·2 in Edinburgh. The fatal cases of scarlet fever, which had been 3 and 2 in the two preceding weeks, rose again to 4 last week. The 4 deaths referred to whooping-cough showed a slight further increase upon the numbers recorded in recent weeks; and the 2 fatal cases of measles showed a further decline. The 150 deaths in Dublin last week included 25 of infants under one year of age, and 35 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further decline from the numbers recorded in recent weeks. Ten inquest cases and 9 deaths from violence were registered; and 56, or more than a third, of the deaths occurred in public institutions. The causes of 8, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN WILLIAM J. CROFTON, half-pay, is placed on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel Haliday, Bombay Establishment, 13th Regiment of Bombay Infantry, has been permitted by the Secretary of State for India to retire from the service. Surgeon-Major C. M. Thompson succeeds Surgeon-Lieutenant-Colonel H. D. Cook as Medical Officer at Octacamund. The services of Surgeon-Captain Mason, A.M.S., are placed temporarily at the disposal of the Government of Bombay for employment on plague duty.

ARMY MEDICAL RESERVE OF OFFICERS.

The under-mentioned Surgeon-Captains to be Surgeon-Majors: — Q. Chalmers, and J. J. de Zouch Marshall. Surgeon-Captain Harry Thornton Challis, 4th Volunteer Battalion the Essex Regiment, to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment: Surgeon-Lieutenant J. Hamel, M.B., resigns his commission. 3rd (Sunderland) Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant R. E. Beveridge, M.B., to be Surgeon-Captain. 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant J. H. Gough resigns his commission. 3rd Volunteer Battalion the South Wales Borderers: James Abernethy, M.B., to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Lieutenant H. C. Reid, M.B., to be Surgeon-Captain.

THE MILITARY DISASTER IN TROCHI VALLEY.

The treacherous attack on an Indian force in Trochi Valley, on the Indo-Afghan frontier, is a rather serious affair. Apart from the loss of life which has to be deplored it must lead to a punitive expedition against the tribesmen, the mere cost of which is embarrassing to the Indian Government at the present time, when there are so many calls upon the Indian Treasury. That the attack was a preconcerted act of treachery there can be no doubt; and it was fortunate, under the circumstances, and seeing that it was quite unexpected, that the whole force was not massacred. As it was, the Indian troops had to make a fighting retreat for a distance of four miles towards Sherani Valley, hotly pursued and hardly pressed by the Pathan tribesmen. Surgeon-Captain Cassidy was one of the wounded —the wound is stated to be in the knee—but we are glad to say that he is reported to be doing well. The Trochi Valley is close to the Kuram route, through which the advance was made in the last Afghan war to avenge the massacre of the Cavagnari mission at Cabul. The inhabitants belong to the fanatical Waziri tribes, and the valley is an important position, as it forms a short cut to Guzni, in Central Afghanistan. It is not the first time within recent years that the tribesmen have attacked a British force in that neighbourhood.

ENTERIC FEVER IN INDIA.

The Anglo-Indian papers received by the last mail contain, we regret to say, intelligence corroborative of the truth of our remarks that the periods of maximum prevalence of enteric fever commonly corresponded with that of the heat in India, and that the seasons directly preceding and succeeding the rainy season, the monsoon, were those in which outbreaks or cases of enteric fever were wont to occur. We learn that there have been several fatal cases of this fever at Agra, Sialkote, and Rangoon. There have been between fifty and sixty cases, several of them fatal, in the York and Lancaster Regiment since their arrival at Agra. It will be remembered that this was the regiment shipwrecked in the *Warren Hastings* on its way to India, which exhibited such an admirable spirit of discipline on that occasion. The *Pioneer Mail* of the 26th ult. states that the cause is ascribed to the water, the supply of which is obtained from the water-works; but in that case it may be confidently expected that the prevalence of the disease will not have been limited to the York and Lancaster Regiment, but will have extended to other people obtaining their supply from the same source. There is frequently a diminished prevalence of the disease during the monsoon, with a subsequent rise; but we hope the worst of the outbreak is already over.

DEATHS IN THE SERVICES.

Ethelbert Henry Blake, M.D. Edin., A.M.D., Deputy-Inspector-General of Hospitals, at Bedford on the 6th inst., in his seventy-ninth year. He was appointed surgeon in 1841, surgeon-major in 1853, surgeon-lieutenant-colonel in 1861, and retired with the rank of Hon. Deputy Inspector-General in 1867. He served with the 98th Regiment in China (medal), was present at the storm and capture of Chin Kiang Foo, and was in the Eastern Campaign of 1854–55, including the battles of Alma and Inkerman, the seige of Sebastapol, and repulse of the sortie on Oct. 26th, 1854 (medal with three clasps, and Turkish medal).

Staff-Surgeon Henry Clerke, R.N., on the 25th ult., at Boulogne-sur-Mer, aged fifty-two years. He was appointed a surgeon in the Navy in July, 1868, staff-surgeon in December, 1879, and retired in September, 1881.

THE PLAGUE.

The great improvement which has of late taken place in regard to the prevalence of the epidemic in India continues, according to the latest reports from that country, and public confidence in regard to it is pretty well re-established. A report from Constantinople of the 13th inst. regarding the appearance of the disease in the Red Sea may, however, be of serious import if true. Bubonic plague is stated to have broken out at Djeddah on the Red Sea, six of the cases having proved fatal. The Turkish Government is taking active measures to arrest the outbreak.

"URIC ACID IN THE BLOOD."

To the Editors of THE LANCET.

SIRS,—It may be that I am doing Dr. D. F. Shearer an injustice in thinking that he is not practically acquainted with the Gowland Hopkins method for the estimation of uric acid; but it appears to me that he has ventured on the dangerous ground of criticising a process that he has never employed. The process that I described for the estimation of uric acid in the blood consisted of two parts—an extraction process and an estimation process. The former part of the process stops short of the washing of the uric acid, during which there is a loss of from one to two milligrammes of the acid by solution. As I was never able to extract any uric acid from normal blood there was none to estimate, and consequently there was none to wash. The murexide test was applied in every case in which I examined blood for uric acid. It is true that I did not refer to those negative experiments in the Goulstonian Lectures, but the time at my disposal for the delivery of the lectures necessitated the omission of mention of a large number of experiments. It would have been as well if Dr. Shearer had stated on what calculation he based his assumption that an average proportion of one part of uric acid in 1,000,000 of blood would be sufficient to furnish the uric acid found in the urine. The assumption is, I believe, incorrect. If the ratio of the urea elimination in the urine to the quantity of urea known to be present in the blood be taken as representing the ratio between the elimination of uric acid and its supposed amount in the blood, then human blood should contain from five to ten parts of uric acid in 1,000,000. The blood of birds would necessarily contain a much higher proportion than that, assuming that uric acid is present in the blood. Such quantities would readily be found if present.

I am, Sirs, yours very truly.

Weymouth-street, W., June 9th, 1897. ARTHUR P. LUFF.

THE LATE DR. LOCKHART ROBERTSON.

To the Editors of THE LANCET.

SIRS,—As a colleague of the late Dr. Lockhart Robertson (as chaplain of the Sussex Asylum, Haywards Heath, 1859–1867), I was interested in the obituary notice in THE LANCET of June 5th. May I be permitted to mention the share which he took in the formation of the "After-care" Association on behalf of poor friendless female convalescents "on leaving asylums for the insane"? As the result of a conversation between Dr. Robertson and myself a meeting was held through the influence of the former, and by kind permission of Dr. Bucknill at his house, 39, Wimpole-street, on June 5th, 1879. There were present Dr. and Mrs. Bucknill, Miss Cons, Dr. Lockhart Robertson, Dr. D. Hack Tuke, Mr. W. G. Marshall, Dr. Harrington Tuke, &c. A paper on the subject of "After-care" printed in the October number of the *Journal of Mental Science*, was read by the Rev. H. Hawkins. It was moved by Dr. Lockhart Robertson, and seconded by Dr. Hack Tuke, that "this meeting do form itself into an association." The names of Dr. S. Williams and Dr. Savage were, at Dr. Robertson's request, added. It was also moved by Dr. Robertson "that Dr. Bucknill be invited to take the office of president," subsequently held by the late Earl of Shaftesbury and the Earl of Meath. Later in the same year Dr. Robertson again attended and spoke at a meeting at the President's house, and in 1881 he was present and spoke at an anniversary gathering at the house of Dr. Andrew Clark, 16, Cavendish-square. Dr. Robertson's various engagements prevented his attendance at meetings in after years, but at the time of his death he was one of the vice-presidents of the "After-care" Association. These few lines from a former associate in work may serve to indicate the interest taken by his distinguished colleague in the institution of the society.

I am, Sirs, yours faithfully,

HENRY HAWKINS,

Hon. Sec. "After-care" Association; Chaplain of London County Asylum, Colney Hatch, 1867–97.

June 12th, 1897.

"A METHOD OF UNITING THE DIVIDED INTESTINE."

To the Editors of THE LANCET.

SIRS,—Under date May 22nd, 1897, I notice in THE LANCET a description by a London surgeon of a reputed new method of uniting a divided intestine. I desire to call attention through your journal to the fact that this operation was devised by me in 1891. It was published in 1892, a copy of which publication you can find in the library of the Society of Science, Letters, and Arts of London, England, which I forwarded at the request of the secretary of the society. I have demonstrated it from year to year to the students at the West Virginia University, performed it many times on living animals and the human cadaver, and it is now, and has been for some six weeks past, in the hands of the editor of the *New York Medical Journal* awaiting its turn for publication. I think the priority of the above-recorded facts should entitle this side with at least the first description of the operation without in any way detracting from the credit due to the originality of the excellent English surgeon.

I am, Sirs, yours faithfully,

J. W. HARTIGAN, M.D., F.R.M.S., &c.,

Professor of Biology in the West Virginia University.

Morgantown, West Virginia, June 4th, 1897.

South Kensington Museum. We do not know of any learned society with the exact title he mentions.—ED. L.

THE MIDWIVES REGISTRATION BILL.

To the Editors of THE LANCET.

SIRS,—Undoubtedly the suggestion of Sir J. Blundell Maple with regard to the Midwives Registration Bill is an excellent one, but would it not be more satisfactory to nurses, patients, and practitioners alike to allow any registered medical practitioner to be called in to inspect and to notify the case to the medical officer of health?

I am, Sirs, yours faithfully,

June 8th, 1897. HEBAMME.

"THE NEW LUNACY BILL."

To the Editors of THE LANCET.

SIRS,—I beg to draw your attention to a clause in the new Lunacy Bill which has been lately introduced by the Lord Chancellor in the House of Lords. The clause, No. 5, is this: "Whereas it is expedient to extend the disqualifications for signing medical certificates in support of a petition for a reception order, there shall be added at the end of Subsection 1 of Section 32 of the principal Act the words, '(*e*) the person who makes the reception order,' and at the end of Sub-section 3 of the same section the words 'or any officer or servant in the employment of such committee, or in a licensed house under an order made on the application of or under a certificate signed by a licensee of any licensed house, or any person in the employment of any such licensee.'" By this it will follow that every licensee and everyone in such employment, which will include lay proprietors and ladies and visiting physicians, will be deprived of the ordinary privilege of choosing an asylum for any afflicted relative which every citizen now enjoys. I venture to think that this would be a monstrous iniquity. In addition, no licensee or anyone employed by a licensee may sign a certificate for any licensed house. You are probably aware, Sirs, that at the present time there is great difficulty in getting certificates signed by ordinary practitioners, and many totally refuse to do this. Public asylum officers are most of them debarred from private practice, and in London their number is extremely small. This clause will prevent almost all the experts in London from signing certificates for private patients; and, besides the inconvenience, I look upon the proposed enactment as an insult to the whole medical profession. No doubt it is aimed as a blow at private asylums. The effect will be the increase of lunatics kept in unlicensed houses—a practice which even now is greatly encouraged by the difficulty of getting a magistrate's order and certificates under the Act of 1890. I am, Sirs, yours truly,

June 13th, 1897. Z.

THE BATTLE OF THE CLUBS.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1639.*)

COVENTRY (*continued*).

NEEDLESS to say that I have heard numerous and doleful stories about patients who have suffered from the mistakes and neglect that are the natural result of overwork at the Coventry Provident Dispensary. Thus a case of strangulated hernia was mentioned which had been left for four days without operative treatment. Another member of the dispensary was treated for rheumatism when he was suffering from a spinal abscess. Of course this patient had not been examined. A woman complained that she remained seventeen days in bed before she could get a medical man to visit her. But it is impossible to blame the dispensary staff. It is composed of medical men who stand high in the profession, only it is mathematically impossible that they should give the necessary time to their patients when, besides extensive private practice, they each have on an average 5000 or 6000 dispensary members on their books. Not only does overwork result in neglect and in mistakes, but it gives encouragement to, and opens out a good field for, the incursions of enterprising quacks. Bone-setters have a good opening, because such operations require more time than can be given for consultations that do not bring in more than two or three pence. If a dispensary patient goes to a quack, it is so much work off the medical man's hands without any reduction in his income. Dispensary medical officers have no cause to be resentful against the quacks who relieve them of some of their most troublesome cases; but all this tends to lower the whole tone of medical practice, and it is high time that energetic measures should be taken against this degradation of the profession.

The next important incident that occurred was the refusal of the medical journals to insert an advertisement of the Coventry Dispensary when a vacancy occurred on its medical staff. The institution was thus placed beyond the pale of honourable recognition by the most authorised organs of the profession. The members of the dispensary medical staff now sought to defend themselves, and their letters were published in the local and in the medical press. They urged that the dispensary was not a charity, but a provident institution founded for the benefit of the working classes. The dispensary, they said, was governed by a committee of twenty-four persons, twenty-two of whom were elected annually by the members from their own ranks. The two other committee men were members of the medical staff. Doubtless a few persons who had entered as workmen had now acquired some wealth, but the working-class character of the institution was fairly well maintained. Whatever abuse there might be, similar abuses existed in other clubs, and when the members of the profession met in 1892 to reform these abuses a great deal of good might have been achieved. In the opinion of the dispensary medical staff, the movement, however, degenerated into an attack upon the dispensary and the dispensary alone. The medical staff of this institution were most anxious to establish a wage limit; but the violence, the lack of courtesy, and the animus of the other medical men produced just the contrary effect, and the resolution that pecuniary position should be no bar to admission was adopted as a sort of reply to these attacks. The adoption of this defiant resolution was deeply regretted by the medical staff, and they promised to use all their influence so that it should be rescinded. They declared that they had "opposed the resolution to the last, and afterwards presented to the committee and entered in the minute book a solemn protest against the whole proceedings." Also in a letter drawn up in November, 1894, and signed by the five dispensary practitioners, the following explanation is given: "For the consideration of the reform movement only two meetings of the profession were held to which we were invited. Three of our number attended the first, while the whole staff attended the second, and again expressed approval. When, however, we were asked to join in this bitter and unwise attack upon our institution we refused, but with a most important qualification, as will be seen from the following quotation from our letter with regard to it, dated Jan. 23rd, 1893. 'While sympathising to the fullest extent with the object in view (medical reform), we feel sure that as a medical committee officially connected with the institution we can do far more to remedy and prevent abuses than by joining a self-constituted committee having no connexion with or power over the management of its affairs.' Not only did we sympathise, but we brought the matter so forcibly before our committee that a special committee was appointed to inquire into the questions at issue, and important modifications were drawn up and agreed to that would have done much to check the abuses complained of, and we also promised that the objectionable rule prohibiting us from meeting medical men not on our own staff in consultation upon dispensary cases should be disregarded (we had no power to abolish it) and that when asked we should meet them as in private practice."

Thus it will be seen the dispensary medical staff took up the argument that reform must come from within, and that pressure from without had produced a reaction against such reform. To my mind, this argument shows that the true spirit which should govern all such efforts had not dawned in the minds of those concerned. If the negotiations for reform were limited to the members of the dispensary on the one side and the dispensary medical staff on the other, this would simply result in haggling and bargaining between

[1] A reprint of the previous articles on the above subject has been published in book form entitled "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1s.

Hosted by Google

persons fighting for their own individual interests. A greater and a nobler cause is at issue. First and foremost, the public has to be protected from the evils, the danger to health, which the abuse of such institutions as this provident dispensary must occasion. Secondly, the profession as a whole must be rescued from the degrading effect of the wholesale and cheap medical relief which dispensaries organise. The strength of the agitation depends on the faithfulness of its adherence to the general interests first of the public and secondly of the profession; and the dispensary medical men would lose all their moral power if they appeared to be pleading for their own interests instead of defending those of the public and the profession at large. Naturally when it was found that they were ready to sever themselves from the other medical men of the town their influence was lost, and the members of the dispensary, instead of establishing a wage limit, proceeded solemnly to declare that the possession of wealth should not be a bar to membership.

It is curious that in all this controversy the interest of the public has not been very clearly and emphatically stated. Mr. T. M Daffern, who has taken a leading position in resisting the demands of the medical men, argued that the dispensary is not a charity, because it pays, and pays well, the medical men in its service. Writing to the *Coventry Herald*, March 1st, 1895, Mr. Daffern says: "May I remind your readers of the state of affairs early in 1893, prior to the passing of the resolution. Of the subscriptions to the dispensary the ordinary members paid £3114, against £18 by the honorary members. For this £18 the honorary members received an equivalent in tickets admitting sick persons as members. Five of the medical staff received an average of £349 13*s.* 8*d.* each from the institution. The sixth, only appointed during the year, received £55 19*s.* 6*d.* They were also allowed to take private practice. It will thus be seen that the ordinary members were themselves properly paying for the benefits they were receiving." This statement, on the contrary, shows, and very clearly, that the medical staff is not properly paid. For 25,000 members, not six or five, but at least twelve medical officers should be employed, and this would reduce the above remuneration to one half the sum for each. The public should know that one medical man cannot possibly attend, thoroughly examine, and give good, thoughtful, and lengthy consultations to the sick out of a population of about 5000 persons, particularly if he has also an extensive private practice. There is no avoiding this dilemma. Such wholesale contract work can only pay if it is "scamped." At this rate of remuneration a proper consultation must be a work of charity; and I put it to the Coventry Provident Dispensary patients, Do they, on an average, obtain the professional ten minutes or a quarter of an hour? If they do they are in receipt of charity; if they do not, then at times public health must be endangered and a public injury is brought about. The honour of the profession is compromised and medical practice is degraded. It is no use saying that each member of the medical staff receives more than £300 a year, the question is, What do they receive per consultation? If they receive less than the minimum fee per consultation, their work is a work of charity when it is efficiently accomplished. If Mr. Daffern had shown that the average of £349 paid in the year to each of the medical staff represented a fee of 2*s.*, or even of only 1*s.* 6*d.* for each consultation given it would be satisfactory. This would prove that the medical men had given only an average of ten or twelve consultations per day, and could therefore well afford to devote about fifteen minutes to each patient. But, in answer to Mr. Daffern's letter, the *Coventry Herald* of March 8th, 1895, published the following:—

"SIR,—My attention has been drawn to a letter in your paper on the Dispensary question. Mr. Daffern has been somewhat unfortunate in the time chosen for his communication. Last week it was published that 3000 prescriptions had been made up at the Dispensary during four days. The thought strikes one, who made up those prescriptions, and again, who wrote them! Unless prescribing can be done by machinery it can hardly be said with Mr. Daffern that 'the Dispensary system is not a sweating one.' Let us make a calculation. As most influenza patients must be seen at home, it is reasonable to allow ten minutes for each prescription; we can hardly imagine that less would suffice. It follows that the six Dispensary doctors must have been hard at work for over twenty hours each day, with an interval of four hours for private practice, sleep and refreshment! In the interests of those for whom the Dispensary was intended, I ask, is such a state of things desirable?" The letter was signed "F.R.C.S."

That such practice is degrading is further shown by the testimony and action of Mr. J. L. Callaghan. Mr. T. S. Allan, one of the dispensary medical officers, on retiring, sold his practice to Mr. Callaghan. The latter did Mr. Allan's work at the dispensary as locum tenens for six weeks, as he had been told there was nothing unprofessional in this work, and hoped ultimately to succeed Mr. Allan on the dispensary medical staff. But his few weeks' experience at the dispensary soon altered his views. The Coventry papers, the *Herald* of July 17th, and the *Standard* and the *Reporter* of July 18th, 1896, inserted the following copy of a letter which had been sent to them for publication, and had been addressed to the chairman of the Coventry Provident Dispensary. It ran as follows:

"13, Queen's-road, Coventry, July 14th, 1896.

"SIR,—As I have led the members of your committee to understand that I would be a candidate for the vacancy on the medical staff caused by the resignation of Dr. Allan, to whose practice I have succeeded, I think it right to let you know my reasons for declining to allow my name to appear among the list of candidates.

"During the six or seven weeks in which I acted as deputy medical officer to the dispensary I discovered the working of the institution to be of such a nature that I fail to understand how any medical man with any respect either for himself or his profession could allow his name to be connected with it, and therefore I have decided to withdraw my candidature.

"I may be at a pecuniary disadvantage in not obtaining this appointment, but as a stranger coming to Coventry, and wishing to uphold the honourable traditions of a learned profession, I cannot see my way to accept an appointment in any institution which is not approved of by the majority of medical men.

"As surgeon to the Public Medical Service, I hope to be able to devote more time to each patient than I could if attached to your institution, and at the same time conduct my practice on lines not distasteful to the majority of the members of my profession.

"Yours faithfully,

"J. LESLIE CALLAGHAN."

That the staff of the Public Medical Service can devote more time to their patients naturally results from the rules of that institution. There is to be a limit for the number of members to be inscribed on any medical man's list. This number has not yet been absolutely fixed by the adoption of a resolution, but it is generally understood that no medical officer of the Public Medical Service must have more than 2000 members on his list. Then, as the service is not a monopoly, but open to all the medical men of the town, there is no danger of some having too much work and others too little. To the public this is the best of guarantees. The interest of the public is to see that no medical man has too much underpaid work. All medical men are willing to do a certain amount of work either gratuitously or for very inadequate pay, but this charitable disposition must not be imposed upon if the temptation to "scamp" the work is to be avoided. The Public Medical Service have now from 5000 to 6000 members on their books, and the success is such that no levies have been necessary. Not only have the medical men not been called upon to pay up the remaining £3 for which they rendered themselves liable, but the £2 they gave on joining have been refunded, and there is a balance in the bank of from £25 to £30. During the first year the medical staff received 2*s.* per member, now they receive 2*s.* 6*d.* per member, and the 10*d.* which remains after the druggists have been paid not only covers the cost of collecting but all the incidental expenses. Thus the organisation of medical aid by the medical men themselves without any intermediaries has proved a financial success.

In dealing with other abuses besides those connected with the provident dispensary the Public Medical Service has also met with a large measure of success. When this association was first formed, it was understood that all private practitioners' clubs should be given up, and the members invited to join the Public Medical Service. Six medical men who were in the service of the Star Benefit Society, the National Medical Aid Association, and other insurance and speculative concerns were induced to relinquish their appointments and bring over as many of their members as possible to the Public Medical Service. To meet this strike the insurance companies were only able to import one medical man from the outside, who still remains in Coventry. Six practitioners belong to the Provident Dispensary, one has a large private club of his own which counts some 2000 members; this he would not give up. Another, on the ground of old age, did not feel disposed to take an active part in the movement, but is not in opposition; he remains neutral. Altogether eleven medical men have joined the Public Medical Service, though only nine are disposed to attend the members. Thus it will be seen that, setting aside the dispensary medical officers, great unanimity prevails among the remaining members of the profession at Coventry, and even the dispensary medical officers are more in agreement with their fellow practitioners than appears on the surface.

Calling upon some of the medical officers of the dispensary,

Hosted by Google

I found that they very frankly recognised the existence of abuses, but had concluded that if they resigned it would only mean the calling in of outsiders to take their places. They had been recently assured that in Birmingham alone there were some fifteen medical men all ready to come to Coventry if invited by the dispensary. This assertion is, however, open to doubt. When, many years ago, the late Dr. Fenton was appointed there were no less than twenty-seven applicants for the post he obtained. About three years ago, to fill up another vacancy, there were not more than four applications, while for yet another vacancy, occurring less than a year ago, there were only three candidates. Of these three, only one was a local practitioner, so that his election was practically uncontested. It seems probable that none but inferior men will accept service in an institution which the organs of the profession refuse to recognise. The strength of the Coventry Dispensary rests on the fact that so far the members of its staff are men of undisputed high standing. The question arises whether the people who drive in their own carriages, who live in villas and yet are members of the dispensary, will be satisfied with medical men of inferior standing. Perhaps the medical staff of the dispensary exaggerate the danger of outsiders stepping in to take their place. Besides, if they were to leave the dispensary and join the Public Medical Service, they would bring over a considerable number of the dispensary members with them. As they would receive for each member thus brought over a much larger sum than they obtain from them as members of the dispensary, they might not perhaps experience any very great loss; also some of the Public Medical Service practitioners expressed to me their willingness to hand over some of their own patients to the dispensary medical men so as to cover any such loss if the staff of the dispensary would agree to join them. As for any personal animosities, they would be at once forgotten if the dispensary staff would only step out and stand shoulder to shoulder in union with the majority of the Coventry practitioners. But still the dispensary doctors adhere to their former policy of effecting reforms from within. They are now again negotiating with the dispensary committee for, I believe, the imposition of a wage limit and a distinct definition of the class of persons to be admitted as members of the dispensary. It was, however, explained to me that they did not wish to publish details about negotiations that are still pending. Also their case has been submitted to the arbitration of the Birmingham Branch of the British Medical Association, and they do not care to discuss the matter publicly till they know the result. One of the dispensary medical officers, however, pointed out to me that they had not been idle and had obtained some improvements. It has already been explained that when the medical men in the service of the Star Benefit Society left that insurance company so as to join the Public Medical Service, the dispensary took in all the members of the Star Benefit Society, thus helping a financial company to dominate the medical profession. The dispensary has now, however, realised the unfairness of its action, and about a year ago refused to renew its contract with the Star Benefit Society. This reform—one might almost say this act of repentance—is cordially approved by the members of the Public Medical Service, and may be considered as an important step towards a reconciliation between the two parties.

Still there is the great financial question that bars the way. As a dispensary medical officer remarked to me, "We have families and children. The dispensary, roughly speaking, brings us in £1 a day. We cannot lightly give this up. If in so doing we were to succeed in bringing about the desired and desirable reforms, we know full well that we should be loudly applauded by all the profession. But if we fail we also know that we should not receive a particle of help from anyone, and we should have to endure poverty and perhaps reproaches for engaging in a struggle without having ensured the means of success." In his opinion the matter ought to be taken up in high quarters and before they were called upon to resign, some guarantee ought to be given that others will not step in and take up their position. The main source of income cannot be given up merely on a question of principle. For a material sacrifice of so crushing a character, some sort of material guarantee and compensation must be forthcoming. As matters now stand the dispensary does not increase the number of medical men on its staff unless their average income exceeds £350 a year. Considering the cheap terms for the admittance of children, that clubs are accepted at 3*s.* per adult member, and that there are fifteen clubs attached to the dispensary, it will be seen that an enormous number of members must be enrolled before the income of the six dispensary medical officers exceeds the average of £350 each. A census taken a few weeks ago shows that the population of Coventry now amounts to 60,990 persons; yet (and including the boycotted practitioner who is in the service of the insurance company) there are only twenty-one medical men. But for the dispensary and the clubs there would be room for more, particularly as the working classes earn good wages and the necessities of life are very cheap. But what is to be done when, for instance, a manufacturer who pays £50 a week in wages belongs to the dispensary and pays only 4*s.* 4*d.* a year for his medical attendance; when a number of prosperous tradesmen belong to the same institution, together with many of the workmen who are well able to pay small fees, and could afford to be independent of charity for all but prolonged illnesses or expensive surgical operations. But the people of Coventry have lost the habit of paying medical fees, and the Public Medical Service is at a great disadvantage, because when they seek to impose their wage-limit, the persons affected have only to apply to the dispensary, where they are at once admitted, and this at a lower rate of subscription. Then the high-class character of the medical men on the dispensary staff renders it still more difficult for the Public Medical Service to compete against this institution. As a rule, institutions that are condemned by the medical profession are not served by men of such high reputation, and enough has now been said to show that even without this factor there is good reason for condemning the Coventry Provident Dispensary.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Health of Liverpool.

THE death-rate of Liverpool is nearly always an uncertain quantity, being much affected by outside influences. At the last meeting of the health committee Dr. Hope accounted for the increased death-rate by the prevalence of measles, in consequence of which several schools have been closed; also by an influx of persons from other towns dying in the city hospitals. Eight of such cases had come from Bootle, whilst others had been brought to the hospitals from Conway, Garston, Crosby, and Barrow, accounting altogether for eighteen deaths, which, properly speaking, ought not to be credited to Liverpool. An unusually large number of infants had died from suffocation; no less than nine inquests where such a verdict was returned having been held last week on children under twelve months old. At the same time the death-rate cannot be considered exceptionally high at 23·3 per 1000 of the population. Dr. Hope has been deputed to attend the International Medical Congress to be held at Moscow in August next. The health committee have also authorised Alderman J. Houlding to accompany Dr. Hope to Moscow.

Birkenhead and the Queen's Jubilee.

The Mayor of Birkenhead has opened a fund for carrying out a commemoration scheme having for its objects the extension of the Birkenhead Borough Hospital by the addition and furnishing of a new wing; the establishment of a home for trained nurses; and the providing of free nursing amongst the sick poor of all denominations in their own homes. It is also intended to provide nursing on a graduated scale for those who are able to make small payments, according to their circumstances. A sum of £6000 will be required to carry out the above objects, of which £3775 9*s.* 6*d.* have already been subscribed or promised.

The Cost of the Public Health Department of Liverpool.

The accounts of the city treasurer for the year 1896 have just been issued. The statement includes the expenses of working the public health department, also those of the department of the inspector of nuisances. The sum of £4487 18*s.* 10*d.* was expended on the medical officer of health's department, after allowing for deductions, such as fines, Exchequer contributions, &c. In these accounts are included notification fees for infectious diseases, which amounted to £651 12*s.* 9*d.*; also fees to registrars for death returns, amounting to £181 19*s.* 1*d.* The department of the inspector of nuisances costs the public £5983 7*s.* 8*d.*, allowing

Hosted by Google

for deductions of a similar kind to those of the medical officer's department. The port sanitary payments, which include the maintenance of infectious cases in the various city hospitals, are set down at £4372 17*s.* 11*d.* The cost for the year of demolition of insanitary property amounted to £34,960 12*s.* 9*d.* This amount does not include the cost of property purchased, which is stated to have been £223,626 13*s* 6*d.*, with charges thereon amounting to £37,295 0*s.* 4*d.*

Liverpool and the Montreal Meeting of the British Medical Association.

The medical profession of Liverpool are to be congratulated on the number of official positions accorded to them at the meeting of the British Medical Association to be held in Montreal in August. Mr. Mitchell Banks, senior surgeon to the Royal Infirmary, is to deliver the address in Surgery; whilst Mr. T. H. Bickerton, Professor Boyce, of University College, Liverpool, and Dr. W. Permewan have been respectively appointed secretaries of the ophthalmological, the bacteriological and pathological, and the laryngological sections.

Liverpool Royal Infirmary.

Mr. George Melly has presented the Royal Infirmary with a complete apparatus for the application of the Roentgen rays.

June 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Honorary Degrees of the University of Dublin.

A MEETING of the Senate of Dublin University was held on June 14th for the purpose of considering an address to the Queen, and in reference to graces for conferring honorary degrees by the board. The graces adopted were duly confirmed. They included the honorary degree of Doctor of Science conferred on our recent distinguished visitor, H. Wilhelm His, Professor of Anatomy, Leipzig.

The Visit of the Anatomical Society of Great Britain and Ireland.

The business portion of the proceedings of this society concluded by the address to the Fellows and Members of the Royal Academy of Medicine in Ireland by Professor His of Leipzig on the Development of the Brain and Nerves. On the following morning a party consisting of over twenty members, conducted by Dr. William Haughton, the honorary secretary of the Dublin branch of the society, started by an early train on an excursion to Killarney. The party included Herr Waldeyer, the Professor of Anatomy from Berlin; Professor Lebourg, of Ghent; Professor Thaine, of London; Professor Disse, of Marbourg; Professor Spalteholtz, of Leipsic; and Professor Young, of Owens College, Manchester.

The Irish Medical Association.

The annual meeting of this association took place recently in Dublin, under the chairmanship of Dr. T. H. Moorhead, the newly-elected president. A resolution was passed unanimously, instructing the council "to take such proceedings as may seem to them advisable to procure an amendment of the existing Poor-law system, having particular regard to superannuation, annual leave of absence to medical officers, workhouse infirmaries, and the abuses so prevalent in the issue of medical relief tickets."

During a subsequent discussion it was stated by the ex-president, Mr. Meldon, that the failure of the Irish Superannuation Bill of last year was caused by the fact that its passage was blocked by the action of three or four Irish members of Parliament who were alleged to have been influenced by some country Poor-law guardians. After the meeting, the members of the Association dined at the Royal College of Surgeons, where they entertained the Right Hon. Charles Hemphill, Q.C., M.P., Lord Monteagle, and many other guests. Resolutions were proposed by the above, by the President of the Royal College of Physicians of Ireland and the President of the Royal College of Surgeons in Ireland and by the President of the Association.

The Coroner for Dublin.

The salary of the Coroner for the City of Dublin has recently been under consideration and the finance committee of the corporation, have recommended that it be increased from £500 to £600 per annum. It was stated that the average number of inquests held in Dublin during each year is 250. Mr. Kenny, the coroner, is a medical man.

Jervis-street Hospital, Dublin.

The post of gynæcologist to this hospital has recently been filled by the appointment of Mr. T. G. Stevens, formerly assistant master at the Coombe Lying-in Hospital, Dublin.

Poor-law Administration.

The report of the Local Government Board upon the recent inquiry into the affairs of the Glenties Union (co. Donegal) was read at a meeting of the board of guardians held on June 14th. The master is censured and called on to resign, and he has done so; further, the report goes on to say: "From the evidence adduced on the present occasion, as well as at former inquiries, it appears that the management of the affairs of the Glenties Union for some time past has reflected little credit on the guardians. The business of this union appears, owing to the apathy of the rest of the members, to be left practically in the hands of a few guardians, whose administration leaves them open to the strongest suspicion of using their powers to advance their own personal interests. The Local Government Board have retained the minutes of the evidence taken in connexion with this inquiry in order to determine whether a prosecution should be instituted against the guardians concerned in the several discreditable transactions to which attention has been called." A special meeting of the board of guardians has been summoned by direction of the Local Government Board for June 26th to consider this report.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Bicycle from a Medical Point of View.

A LONG discussion has been going on at the Hospital Medical Society as to the benefit or harm to be derived from riding the bicycle, and the debate was all the more interesting from the fact that most of the members taking part in it themselves had experience of the machine in question. M. Petit reported a series of accidents, and cited five recent cases of death occurring in persons either actually riding or who had just left off. He concluded that persons suffering from cardiac affections ought either to abstain from bicycling altogether or at any rate only do so with the most extreme moderation. Phthisical people should for the most part abstain altogether; but, on the other hand, those predisposed to tubercle have in many instances derived great benefit, as have still more those suffering from certain nervous affections, neurasthenia, chlorosis, and constipation. Finally, M. Petit reminded the meeting that various affections of the joints and of the genito-urinary organs in both sexes, incompletely or only recently cured, had been revived or aggravated by the bicycle. M. Hallopeau, replying to M. Petit, said that the bicycle, which was not a physiological method of progression, offered, like all forms of athletics, both advantages and disadvantages. These latter were specially marked in cardiac subjects, in whom cardiac failure supervened. In certain subjects, even when free from cardiac disease, riding provoked painful sensations connected with the heart. He considered it prudent to avoid riding against head winds or up steep hills, and by taking this precaution many grave accidents would be avoided. Some people experienced numbness in the great toes during a prolonged ride, a phenomenon which M. Hallopeau attributed to the pressure of the saddle on the sciatic nerves. M. Rendu had seen symptoms of angina pectoris supervene after a long bicyle ride in a medical man who had never before shown any signs of cardiac affection, and considered that no person over forty years of age should take this form of exercise save in great moderation, so as to avoid a rise in blood pressure and cardiac fatigue. M. Legendre did not believe that the use of a bicycle could create a pathological condition; but undoubtedly it brought out certain maladies which had formerly lain latent; hence the necessity for examining young people before permitting them to commence this form of exercise. He had recently seen several cases of mitral regurgitation appearing in young people who before taking to bicycling had presented no sign of such complaint. Difficulty in nasal respiration owing to a deviated septum was also a cause of cardiac arrhythmia

Hosted by Google

and became markedly so in cyclists owing to their aggravated respiratory efforts. On the other hand, women with certain forms of menorrhagia derived much benefit from the bicycle. M. Ferrand stated that the effort of bicycling is in some sense unconscious, and, to use the language of M. Texier, produces a kind of automatism which prevents the rider from being conscious of over-riding and its dangers. M. Debove knew a medical man subject to attacks of cardiac intermittence which came on either during rest or work, and especially before sleep. Exercise had no effect with regard to them; he could go upstairs or ride a bicycle without bringing them on. He suffered from migraine, but his digestion was good and he was not gouty. M. Debove brought forward this case as showing that cardiac intermittence can occur independently of any fatigue, and that the evils due to bicycling are exaggerated by attributing to the practice results for which it cannot be blamed. M. Faisans considered that it was unfair to charge the bicycle with all the accidents that occurred during riding, as a certain number of these sudden deaths would equally have occurred from any form of exercise. M. Debove considered that the result of the discussion showed that excess in any form was harmful, and that as regarded the bicycle over-riding alone was dangerous. Let unsound persons avoid it altogether and the healthy use it in moderation, and all accidents would be avoided.

Koch's Tuberculin and the Academy of Medicine.

According to French law the sale of serums is only authorised after the Academy of Medicine, by means of a committee, has given its approval to samples and inspected the laboratories where they are prepared. This law was passed to prevent all sorts of serums being put forward by druggists for the sole purpose of advertisement and without any guarantee of asepsis or strength. Very few laboratories obtain the necessary certificate. Koch's tuberculin, to have the right of entry in France for sale, has had to undergo the judgment of the Academy based upon the report of M. Nocard, the assistant director of the Pasteur Institute. The report commences by saying that any French product produced under circumstances precluding the Academy from any surveillance as regards the conditions of its manufacture would certainly be refused. The sample sent in, it continues, amounted to 1 c.c. enough for one experiment only as to activity, and the liquid was turbid and full of bacteria and yeasts. The bacteria were very possibly not pathogenic; but their presence was not reassuring, for it would appear to show that the liquid was not prepared under aseptic conditions, and even if the organisms did no harm to the patient they would probably weaken the power of the serum. The Academy, fearing that if they refused the authorisation altogether their action would be attributed to national jealousy, have authorised the introduction of the lymph provisionally, despite the report of M. Nocard. Many of the papers have published articles expressing regret at this decision.

Scandal at a Lying-in Hospital.

The Municipal Council gave a whole sitting to the consideration of the case of a parturient woman who died from not having been admitted in time to the hospital where she applied for relief, and the meeting took advantage of the occasion to deliver a violent attack upon the organisation of hospitals in general. It appeared that the woman had just been delivered of twins, but that only one placenta had come away. She applied in the middle of the night at the hospital, where the midwife on duty would have admitted her except for the fact that there was no vacant bed. She applied to the head midwife and the director of the hospital, who declared that in the absence of a bed the woman could not be admitted. They telephoned, however, to two or three other hospitals, and finally found a vacant bed for her at the Charity Hospital, to which the woman was taken as soon as possible and there delivered. Five hours afterwards she died. The chief of the Assistance Publique reprimanded the director of the hospital and the head midwife and suspended the midwife on duty. The Municipal Council demanded an inquiry so as to make it appear whether or no the responsibility rested with the director only, and regretted that an inferior, who was probably not responsible, had been punished with a view to sparing the chief. The discussion was very heated despite the fact that the Director-General reported that the result of the post-mortem examination showed that the woman had died from causes quite unconnected with the delay in her delivery or in her admission to a hospital.

The Provident Societies.

In the course of a discussion which recently took place in the Chamber on the new law which has just been introduced with regard to provident societies great leniency was shown to these societies, which do grievous harm to medical men by reason of their miserably low fees. It was demanded on behalf of the societies that they should have the right to gratuitous legal assistance in case they had a law-suit, but the legal profession protested vehemently against this, saying that bodies which had a capital of 40,000,000 francs and a membership of 500,000 in France should not in reason be admitted to favours reserved for the indigent alone. The Chamber, where there are many lawyers, saw the justice of this argument and refused the application, but not one of the numerous medical deputies said a word with regard to the shameful tariff which these societies impose on medical men. These members were more concerned for the pockets of their constituents than for the interests of their brethren. On the motion of a deputy, not a medical man, it was decided to insist that there should be two members of the Academy of Medicine on the superior council of the provident societies, and it is possible that these two gentlemen may, if they will, play an important *rôle* for the benefit of their profession.

June 14th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Congress of Internal Medicine.

THE fifteenth annual meeting of the Congress of Internal Medicine, the proceedings of which will be reported in a forthcoming number of THE LANCET, was held this year in Berlin. This Congress dates from the year 1881, up to which time the annual congresses of the Association of German Naturalists and Medical Men offered the only opportunity for the holding of discussions on clinical medicine; the surgeons, however, had their first special congress as early as 1871. The original organising committee, composed of Professor von Leyden, Professor Gerhardt, Professor Kussmaul, and Professor Seitz, proposed to make Wiesbaden the seat of the congress, avoiding a university town in order that no individual university might have a preponderating influence on the proceedings. All the meetings were accordingly held in Wiesbaden until 1889, except that in 1884 the congress took place in Berlin as a token of respect to its honorary president, the late Professor von Frerichs. In 1889 it was decided to meet only every second year in Wiesbaden, and in the intervening years to meet alternately in Munich, Leipzig, Berlin, and Vienna, by which arrangement it was hoped that medical men in distant parts of the German Empire and in Austria who might be unable to make a long journey to Wiesbaden would have an opportunity of taking part in the proceedings. This year's Congress was opened on June 9th in the great hall of the Architects House. Professor von Leyden, the president, having been called away the day before to Bukarest to attend the Crown Prince of Roumania, the chair was taken by Professor Moritz Schmidt, of Frankfurt, and the presidential address which Professor von Leyden had prepared was read by the acting vice-president. Internal medicine, it was remarked in the address, has entered on a stage of revolution, and therapeutics are now in favour, the former pessimism and disbelief being, fortunately, things of the past. Physicians no longer accept any dogmatic system and no longer try to cure the illness, but endeavour to cure the patient regarded as an individual. Medicine must not only be an exact science, but must also be an art—the art of curing. Two new classes of therapeutical agents have become available during recent years—namely, the antitoxins and extracts prepared from various parts of the animal organism. Behring's diphtheria antitoxin has been an undoubted success; as to the other antitoxins, such as those of tetanus and erysipelas, no definite judgment can be pronounced. The thyreoiodin of the late Professor Baumann was an important step in the use of animal extracts. Great improvements have been made in dietetic treatment, as well as in the mechanical and hydro-therapeutic divisions of the subject. The individual practitioner is no longer able to undertake

Hosted by Google

all the multiplied ramifications of therapeutics, and the subdivision of medicine into a number of special branches is inevitable, though it is no doubt from some points of view to be regretted. The training of the medical student has also become more difficult owing to the enormous mass of subjects which he is expected to know and which increases from year to year. Moreover, in the midst of this accumulation of details the fact must not be lost sight of that the principal aim of medical education ought to be the cultivation of the faculty of observing rightly. After the inaugural discourse the usual addresses of welcome were delivered by the representatives of the Government, the city, and the Berlin medical corporations respectively. Professor Virchow, speaking as President of the Berlin Medical Society, made the unexpected remark that there was some degree of likeness between the new antitoxin theory and the old humoral pathology. He was of opinion that the utility of the antitoxins was satisfactorily proved, but that from a theoretical point of view their action was still as obscure as the action of Jenner's vaccine. On the conclusion of these ceremonial proceedings the practical business of the Congress commenced.

The Antitoxin Control Office.

The Royal Antitoxin Control Office, over which Professor Ehrlich presides, will soon be removed from Berlin to Frankfurt. The reason alleged by the Government for this decision is that the principal antitoxin factory, the Hoechster Farbwerke, being situated in a suburb of Frankfurt, the work of the Control Office was much interfered with by the distance between that city and Berlin. But notwithstanding this distance the State control of the Hoechst factory has hitherto been so effective that its antitoxin has been declared by competent bacteriologists to be the best that is made.[1] Other reasons must, therefore, have induced the Government to come to this decision, and, in fact, the motives were of a merely financial nature, for the Government, departing from its former policy of open-handedness in this matter, has recently been but little inclined to spend money for scientific and especially for medical purposes, and the town council of Frankfurt having offered to provide both a large sum for the immediate requirements of the new office, and also an annual subsidy for its support, the Government at once accepted this proposal. The city of Berlin, which has rightly declined to spend the money of the city for institutions which it should be the duty of the State to support, will therefore lose the Control Office, and the departure of Professor Ehrlich will be much regretted by the medical profession here. Although Professor Ehrlich has never been an academical teacher in the strict sense of the word as far as the bulk of students are concerned, he has nevertheless exercised a great influence on a select number of students and graduates who worked under him and with him in his laboratory, where so many valuable researches have been conducted. His chair will be taken by Professor Brieger, the head of the clinical department of the Institution for Infectious Diseases.

June 14th.

Obituary.

KARL REMIGIUS FRESENIUS.

THE death is announced of Professor Karl Remigius Fresenius at Wiesbaden from an apoplectic attack at seventy-nine years of age. Fresenius was the director of the chemical laboratories at Wiesbaden, and his name will ever be remembered in connexion with his system of chemical analysis. It may be said, indeed, without fear of contradiction that Fresenius was the founder of analytical chemistry. His work in this direction is admittedly of a purely classical type. His various contributions have a distinct bearing upon medicine, since Fresenius was the author of, as he was the great authority on, the analyses of almost all the baths and springs in Europe used in medical treatment. His chief publication, "Chemical Analysis, Qualitative and Quantitative," was translated into English by Mr. A. Lloyd Bullock many years ago. The book has since reached a tenth edition and is even now the standard work of reference on systematic inorganic analysis. Fresenius was a busy man, a close and diligent worker, and a most skilful operator at the chemical bench. Curiously enough, he had at no time contributed any research, but his analytical results always gave evidence of the most painstaking work and of attention to those rarer saline constituents which, though occurring in small quantity, possessed nevertheless some importance.

CHARLES HOLDRICH FISHER, M.D. GLASG., M.R.C.S. ENG., L.S.A.

THIS well-known Kentish practitioner died at his residence at Sittingbourne on May 29th from degeneration of the heart at the comparatively early age of sixty-two years. He always said he should die in "harness," and this was so, for he saw his patients until within three weeks of his death. Dr. Fisher was educated at Glasgow University, where he was a distinguished student and made many lasting friends. He then settled at Sittingbourne, Kent, and became a partner of the late Mr. Ray. He was an especially energetic, active, and tactful practitioner, besides being a most genial and amusing companion and one who always engaged the attention of his hearers. He seldom took a holiday, hunting being his only recreation, and his merry laugh and cheery face were well known in the hunting field. He practised in Sittingbourne for forty years, holding parochial, and, in fact, nearly all the appointments, and he has left behind a large circle of sorrowing friends, especially amongst the poor, by whom he was so well beloved.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Nocquart, Professor of Anatomy in the University of Brussels, in consequence of a dissection wound, at the age of forty-two years.—Dr. Auguste Mollien, Professor of Clinical Medicine in the Amiens Medical School.—Dr. Creus, of Manso, Professor of Clinical Surgery in the Central University, Madrid.

Medical News.

THE RECENT NIGER SOUDAN CAMPAIGN.—Mr. E. Craster, P.M.O. Niger Territories, and Mr. Stanton, M.R.C.S Eng., have been mentioned in despatches.

DIPHTHERIA IN LONDON. — The amount of diphtheria in London in the four-weekly period ended on May 22nd does not compare so favourably with the preceding period as did that with earlier like periods in respect of the metropolis as a whole. The number (730) of notified cases in the four weeks ended on April 24th increased to 777 in the succeeding four weeks, the averages per week being respectively 182 and 194. But whilst in April two districts had upwards of fifty notifications each, there was only one such sanitary area in May. All districts save one were invaded in April, and all save two in May. The registered deaths from the disease were 134 in April, and averaged 33 weekly, the per case mortality rate having been 18·4 per cent. In May the deaths registered were 142, and averaged 35 weekly, the per case mortality having been 18·3 per cent. In the corresponding May period of 1896 the notifications amounted to 890 and the weekly average to 222, the deaths to 161 and the weekly average to 40, and the per case mortality rate to 18·1 per cent. The fatality rate was therefore closely allied on both occasions, but the amount of disease and the number of deaths have fallen in the current year as compared with 1896. In the three completed weeks that have elapsed since May 22nd, the registered deaths from diphtheria in London have been successively 36, 33, and, last week, 39. In the week ended June 5th the 33 deaths corresponded with the corrected decennial average for the twenty-second week of the period 1887–96, three of the deaths being of infants and one of a person over twenty years. Six deaths belonged to Kensington, and three respectively to Islington, Poplar, and Wandsworth sanitary areas. Last week the thirty-nine registered deaths in the metropolis were seven in excess of the corrected decennial average for the particular week. Seven deaths belonged to Shoreditch, four to St. George's-in-the East, and three each to Poplar and Greenwich sanitary areas. All thirty-nine deaths were of young persons aged under twenty years, and five were of infants. In the fortnight ended with last Saturday there were eighteen deaths registered from diphtheria in the outer ring of London, eight occurring in the West Ham registration district.

MEDICAL MAGISTRATES.—Mr. Thomas E. Abbott, L.S.A. Lond., of Gormanston, Tasmania, and Mr. Herbert W. Brownrigg, L.K.Q.C.P., L.R.C.S. Irel., of Broome, Western Australia, have been appointed Justices of the Peace for the district of Macquarie, Tasmania, and for the colony of Western Australia respectively.—Mr. John H. Thomas, L.R.C.P. Edin., M.R.C.S. Eng., has been placed on the Commission of the Peace for Barrow-in-Furness.

VICTORIA UNIVERSITY.—The following have been adjudged worthy of the degree of M.D.:—J. M. Johnson, M.B.: Thesis, Disinfection by means of the Vapours of some of the Members of the Phenol Series; C. E. Ligertwood, M.B.: Thesis, A Form of Alcoholic Cardiac Failure; Frank Radcliffe, M.B.; Thesis, Spread of Tuberculosis in Guinea-pigs; C. H. G. Ramsbottom, M.B.: Thesis, The Isle of Man as a Health Resort.

THE ROYAL AQUARIUM JUBILEE PROGRAMME.—Visitors to London will be gratified to learn that no sensational item is announced among the attractions of this popular place of entertainment during the Jubilee and following week, but some of the attractions which are offered should prove both interesting and instructive. The beautiful living pictures which have proved so popular will be continued, but they will now represent Her Majesty's Accession and Coronation, marriage with the Prince Consort, and a number of tableaux illustrative of the fashions and interesting epochs during her sixty years' reign.

THE LATE MR. J. GREIG SMITH.—At the meeting of the committee of the Bristol Royal Infirmary held on June 8th it was unanimously resolved that a vote of condolence be sent to Mrs. Greig Smith, and the committee also recorded their deep regret at the loss the infirmary had sustained by the sudden death of Mr. Greig Smith, as by his great talents and surgical skill he had contributed in an exceptional degree to the success of the work carried on in the wards. It was further agreed that the re-construction of the operation theatre in accordance with a scheme which had been lately suggested by Mr. Greig Smith himself, and in which he took the deepest interest, should be undertaken as a memorial of him, and that a committee should be formed to receive contributions for this purpose.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The annual general meeting of this society was held at 40, Leicester-square, on Monday, June 14th, the President, Mr. R. H. Woodhouse, occupying the chair.—The librarian, in presenting his annual report, remarked that there had been an increase in the number of members and visitors who had made use of the library during the year, and that the number of books borrowed had been greater than in previous years.—The curator stated that during the year several valuable additions had been made to the museum, including some excellent specimens illustrating pathological conditions of the teeth in the lower animals. He also appealed to members for gifts of "bone dentures," as specimens of this class of work were becoming day by day more scarce, and he was anxious to have in the museum as good a collection as it was possible to obtain.—The report of the treasurer showed that the receipts had exceeded the expenses by the sum of £26 19*s.* 5*d.*, and that the amount invested stood at £4378 16*s.* 3*d.*—Mr. C. Robbins showed a specimen of a "Home-made Denture." It consisted of a base composed of sheet iron, and to this were fixed three blocks of bone, one being placed on each side and one in front. This denture, which did not conform in any way to the shape of the hard palate, had been tolerated for over thirty years, the curious fact being that the bone block showed not the slightest traces of disintegration. Dr. Grevers, of Amsterdam, read an interesting paper on the Relation of the Bite of the Upper and Lower Teeth. He recounted the various classifications adopted by various authors, and illustrated his points by means of an extensive collection of photographs of skulls from the museums of Amsterdam, Vienna, and Paris. The following gentlemen were elected office-bearers for the ensuing year:—Mr. W. E. Harding, president; Mr. W. H. Woodruff, treasurer; Mr. W. A. Maggs, librarian; Mr. J. F. Colyer, editor of Transactions; Mr. Storer Bennett, curator; and Messrs. J. H. Mummery, H. Baldwin, and J. O. Butcher, honorary secretaries. After the announcement of the ballot the retiring President read his valedictory address, the usual votes of thanks being accorded to the retiring officers. The meeting then terminated.

THE annual dinner of the Epidemiological Society will be held at the Grand Hotel, Trafalgar-square, on Friday, June 25th, at 7.15 P.M. The chair will be taken by the President, and tickets (price 10*s.* 6*d.*) may be obtained from Dr. Bulstrode, 4, The Mansions, Earl's-court, S.W.

MR. ALFRED COOPER, F.R.C.S. Eng., has been appointed Surgeon-in-Ordinary to His Royal Highness the Duke of Saxe-Coburg and Gotha, in the room of the late Mr. Wm. Hickman.

THE UNIVERSITY OF WALES.—The number of candidates for matriculation in the University of Wales this year amounts to 425, as against 216 last year and 89 the year before. The Prince of Wales (the Chancellor of the University) has expressed his gratification at this satisfactory proof of its growing prosperity.

A MEETING of the Nottingham Medico-Chirurgical Society was held on May 19th, Dr. Ransom, President, being in the chair.—Mr. Milner showed a case of Molluscum Fibrosum in a woman aged fifty-seven years.—Dr. Tresidder showed a woman, aged forty-five years, suffering from Pigmented Spots on the Nose. He suggested that it might be a case of melanosis lenticularis progressiva.—Dr. Wesley read a paper on Submaxillary Cellulitis. After referring to the anatomical relations of the submaxillary cellular tissue and the distribution of the areolar planes in continuity with it the bacterial element of the disease was discussed. The micro-organism seemed to have been different in individual cases, the most common variety, however, being a streptococcus, this tending to prove that submaxillary cellulitis cannot be truly looked upon as a specific disease. Numerous cases were detailed which showed most of the varieties and the chief complications of the affection. The cases grouped themselves into—first, the very acute ones, in which the constitutional symptoms were severe and which rapidly ended fatally; and, secondly, the less acute cases which have arisen from extension of inflammation from the lymphatic glands, the general symptoms being less severe, and almost always resulting in recovery. Free and early incision was insisted upon in all cases, and the most favourable position for the various cases was discussed. For the anæsthetic chloroform was to be preferred, a local anæsthetic such as ethyl chloride being occasionally useful. In the acuter cases the use of antistreptococcus serum was advocated in addition to incision. Dr. Ransom and Mr. Anderson discussed the subject, and Dr. Wesley replied.—Dr. Bell Taylor read a paper on the Contagious Diseases Act from a Sanitary Aspect. He said that in the army reports of those cases classified as syphilis and invalided as such two-thirds were due to gonorrhœa and nine-tenths of the remainder were due to non-syphilitic sores; neither of these classes presented constitutional symptoms. In the remainder the disease does not present serious symptoms, tertiary signs being rarely seen nowadays. After quoting numerous authorities in support of his hypothesis that exceptional legislation on the subject is not required, Sir H. Campbell-Bannerman and Mr. Shaw-Lefevre were quoted as legislators who had expressed views antagonistic to the Acts. He thought the Acts failed because the disease in woman is often so dormant and with such difficulty detected. He advocated voluntary hospitals. The subject was discussed by Dr. Ransom, Mr. Anderson, Dr. Handford, Mr. Wood, Dr. Bolton, Mr. O'Mullane, and Dr. Tresidder, and Dr. Bell Taylor replied. Finally, the following resolution was proposed by Mr. Anderson, seconded by Mr. Geraty, and carried: "That the society, having considered the question of the prevalence of venereal disease in the army, hopes that the Government will take immediate steps to check its spread."

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"THE SUPPLY OF TETANUS ANTITOXIN."

To the Editors of THE LANCET.

SIRS,—We read with interest Mr. Arthur H. Buck's letter in THE LANCET of June 12th regarding the supply of antitoxins when city warehouses are closed. There should be no difficulty in obtaining supplies of Messrs. Burroughs, Wellcome, and Co.'s therapeutic serums in every large town, and we have no doubt that many chemists, like ourselves, make a point of stocking such preparations. We can supply all or any of the serums, hypodermic "tabloids," and emergency or regular preparations on Sundays, holidays, or when Messrs. Burroughs, Wellcome, and Co.'s offices are closed.

We are, Sirs, yours truly,

Regent-street, W., June 16th, 1897. J. MUNRO AND CO.

THE VALUE OF MEDICAL SERVICE.

A WELL-MERITED rebuke was administered to the executors of a Mrs. Howells, whose estate at her death amounted to nearly £10,000. Mr. T. W. Burwood, of Ealing, attended the deceased lady for cancer of the bowel from Dec. 9th to the 31st, charging 10*s.* 6*d.* a visit for twenty-six visits, including small operations. The trustees, Messrs. Gilbert, of Avenue-crescent, Acton, disputed the claim and paid into court £9 10*s.*, but the jury found for the plaintiff for the full amount. The case was tried before his Honour Judge Bagshawe at the Brentford County Court, and in giving judgment his Honour remarked that "to defend such a case for the trifling difference between £9 10*s.* and £14 seems to me putting the estate of the deceased lady to an expense which it was injudicious to incur." Taking into consideration the fact that the patient lived out of the district and the serious nature of the case, the medical attendant's fees do not seem to have been at all high; but the case illustrates the estimate which a certain class of people have of the value of medical service.

Hosted by Google

CATARRHAL JAUNDICE.

To the Editors of THE LANCET.

SIRS,—I should be very glad if some of your readers would give me their experience of such cases and advise me, especially as to diet, what they have found to answer best. My case is that of a young man, aged thirty-two years, who has also cardiac disease and has been suffering from jaundice for the past four months, otherwise he has been very healthy and did not know of the heart mischief until he was examined at the beginning of this attack. There is slight enlargement of the liver, but little or no pain, and he has lost considerably in weight. The skin and conjunctivæ keep very deeply stained, notwithstanding the long treatment, first with alkalies and Carlsbad aperients, and latterly with dilute nitro-muriatic acid and nux vomica, combined occasionally with digitalis. He is not troubled much with itching or constipation, but the motions keep very pale and the urine deep-red though abundant. As nothing that I have done seems to be of any use, I should be very pleased to have a reply from anyone interested in these cases through the medium of THE LANCET. I am, Sirs, yours truly,

June 14th, 1897. PERPLEXED.

G. G. S. M.—We never give medical advice or recommend medical men by name. Our correspondent is advised to take the opinion of the medical practitioner whom he has already seen, who will tell him if a consultation is required.

THE LATE DR. J. C. LISBOA.

DR. J. C. LISBOA, whose death occurred on May 1st, held a prominent position in medical and scientific circles in Bombay. He was born in Assagaum, a little village in Goa, Portuguese India, in 1823, and went to Bombay for the purpose of studying medicine just four months before the Grant Medical College commenced to receive students. Within a month after passing out of the college on the completion of his five years' course he was made assistant to the surgeon of the Sir Jamsetjee Jejeebhoy Hospital, and assistant to the professor of anatomy in the Grant Medical College. A month later Dr. Morehead, principal of the college, gave him an interim appointment as lecturer on anatomy in the college, and selected him to do duty as a surgeon in the above-mentioned hospital, the records of which for 1851 refer in complimentary terms to his services. The late Dr. Vandyke Carter, in his book on "Leprosy" gives him the credit of having been the first in India to take up the study of that disease. Botany, however, was the subject on which his reputation was mainly founded. Among his numerous writings on this science may be mentioned various papers contributed to the Bombay Branch of the Royal Asiatic Society and the Bombay Natural History Society on the "Mahableshwar Plants," "Plants not mentioned in Dalzell and Gibson's Bombay Flora," "Grasses of the Bombay Presidency," and "Useful Plants of the Bombay Presidency." Two grasses are named after him, Tripogon Lisboæ and Andropogon Odoratus Lisboæ, the latter of which is said by the late Dr. Dymock and his two associates in their "Pharmacographia Indica," to have been discovered by his wife. Dr. Lisboa was elected Syndic (Medicine) of Bombay University, President of the Grant College Medical Society for ten years, and of the Medical Union for four years. He was a member or fellow of many scientific associations, among which may be mentioned the Royal Academy of Sciences of Lisbon and the Linnean Society of London.

Distressed One.—If our correspondent has the various conditions hinted at no time should be lost in consulting the family practitioner as to the course to be adopted. We do not recommend either medical men or treatment.

"THE MORAL EDUCATION OF BOYS."

To the Editors of THE LANCET.

SIRS,—May I answer "Father's" question asked in your issue of June 12th, p. 1649? My essay "Morality," price 1*s.* 6*d.*, tenth edition, is published by Messrs. J. and A. Churchill, 7, Great Marlborough-street. Possibly "Father" may refer to a letter of mine headed "The Grave Social Problem" which appeared in THE LANCET about fifteen years ago. If so, I will with pleasure send him a copy of it on application. By your kindness a few dozen copies of it were printed on slips and sent to me at the time.—I am, Sirs, yours truly,

MAURICE C. HIME

(For twenty years head master of Foyle College, Londonderry).

Hillmount, Londonderry, June 13th, 1897.

*** We congratulate Mr. Hime on the notice which his book has received, for we have had numerous letters answering "Father's" query by referring to this work.—ED. L.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Father" will find what he requires in "The Special Temptation of Early Life," by C. G. Wheelhouse, F.R.C.S., published at the request of the Ripon Diocesan Conference by Messrs. Walker and Laycock, Printers, 37, Briggate, Leeds.

I am, Sirs, yours faithfully,

June 12th, 1897. PATERFAMILIAS.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Will you allow me, through the columns of THE LANCET, to ask if any of your readers can inform me of a home for inebriates where a young man, unfortunately addicted to alcohol, would be admitted in return for his services as servant, &c.? He is very respectable, well-educated, most anxious to be kept from the temptation of "drink," but is now too poor to be able to pay a fee.

I am, Sirs, yours faithfully,

June 12th, 1897. L.R.C.P.Edin.

X. Y. Z.—When a man holds a public position, as the subject of the paragraph in question does, a certain amount of newspaper notice is inevitable, however regrettable.

THE STATISTICS OF THE ANTITOXIN TREATMENT OF DIPHTHERIA.

MR. LENNOX BROWNE writes to us to dispute the inferences we drew in an article in THE LANCET of June 12th, p. 1621, upon the mortality statistics of diphtheria in the hospitals of the Metropolitan Asylums Board since the introduction of the treatment by antitoxin. He thinks that the very low mortality—10·8 per cent. (or 6·4 per cent. if the "moribund" patients be excluded)—amongst those not treated by antitoxin should be taken into account in any comparison of the antitoxin years with the pre-antitoxin years. We fail to see the necessity for this, since it is expressly stated that (save at one hospital) only the very mildest cases, or those which were obviously moribund on admission, were excluded from this treatment. Supposing that every such case had been given a minimal dose of antitoxin, would that have altered his opinion of the remedy? To our thinking the reporters acted wisely in basing their comparative statistics upon the results of all cases admitted during the year, although the argument in favour of antitoxin is immensely strengthened by the fact that the cases in which it was used comprised the more severe types. Nor can we admit with him that the decline in the mortality, which is especially noticeable in 1895 and 1896, is to be attributed to "better local treatment and more vigilant nursing care." If so, how can we explain the much greater proportional decline in the mortality of post-scarlatinal diphtheria?

"INCUBATORS."

To the Editors of THE LANCET.

SIRS,—We notice an inquiry as to where incubators for babies can be procured in England. We keep a stock of these incubators for either sale or hire, we did this at the suggestion of Dr. Champneys, and they will be found on p. 847, Fig. 3227, of our last illustrated catalogue of surgical instruments and appliances. We shall be pleased at any time to show these incubators to your correspondent.

We are, Sirs, yours faithfully,

26, West Smithfield, E.C., June 14th, 1897. ARNOLD AND SONS.

To the Editors of THE LANCET.

SIRS,—If "H. G. C." will refer to Section 1543:1 of the "Medical Digest," 1890 edition, and Appendix, he will be able to obtain all the information he desires. "Father" will also find references to much instructive literature upon the "Moral Education of Boys" in Sections 1083 and 1084 of the same work.—I am, Sirs, yours truly,

June 14th, 1897. RICHD. NEALE, M.D.Lond.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Herald of Wales, Sheffield Independent, Evesham Journal, Rugby Advertiser, Banbury Guardian, Derby Express, Manchester Courier, Bradford Observer, Tamworth Mercury, Kidderminster Times, Western Morning News, Portsmouth Times, Berrow's Worcester Journal, Oldham Standard, Times of India, Pioneer Mail, Science Siftings, Le Temps, Doncaster Chronicle, East Anglian Daily Times, Architect, Salisbury Journal, Devon Weekly Times, Liverpool Daily Post, Walsall Observer, North Wilts Herald, Brisbane Courier, Builder, Croydon Guardian, Sussex Daily News, Birmingham Mail, South Wales Daily News, Glasgow Herald, Daily Chronicle, Chard News, Yorkshire Post, Barnsley Independent, Newcastle Leader, Leeds Mercury, Brighton Gazette, City Press, Bristol Mercury, Public Health Journal (New York), Forest Gate Weekly News, Hertfordshire Mercury, Printing Trades' Gazette, Weekly Free Press and Aberdeen Herald, Mining Journal, Local Government Chronicle, Reading Mercury, Sanitary Record, Braintree and Bocking Advertiser, Local Government Journal, Southern Daily Mail (Portsmouth), Surrey Advertiser, Mandalay Herald, Huddersfield Examiner, Evening Telegraph (Dundee), Tyrone Constitution, Kirkcudbright Advertiser, Loughborough Monitor, Ayr Advertiser, South Africa, Stowmarket Courier, Penarth Chronicle, Lisburn Standard, West Middlesex Herald, &c., &c.*

PANOPEPTON.

PANOPEPTON is the entire edible substance of prime lean beef and best wheat flour, thoroughly cooked, properly digested, sterilised, and concentrated in vacuo, and preserved in a sound Sherry.

PANOPEPTON is *the* food par excellence for invalids and convalescents—that large class of persons who from feebleness or antipathy to ordinary food require a fluid, agreeable, and quickly assimilable food.

PANOPEPTON is at once a grateful stimulant and food.

PANOPEPTON should not be mixed with milk or any other food, but should be taken pure or with cracked ice or aerated water. For an adult, the usual portion should be a tablespoonful several times a day and at bedtime.

CAUTION.—SCHACHT'S REMEDIES.

The Profession is respectfully warned against imitators of Schacht's Perfect Preparations. Articles are being offered that, except in name, bear no resemblance to those whose reputation rests upon a successful experience of more than forty years. The safeguard is to insist on having "SCHACHT'S."

SCHACHT'S LIQUOR BISMUTHI.

Absolutely pure. The original preparation, invented and introduced to medicine by Mr. Schacht in 1855. Its distinct superiority is universally admitted. In ½ lb., 1 lb., 2 lb., and 5 lb. bottles. Dose: One drachm diluted, equivalent to a full dose of the Trisnitrate When prescribing or ordering, please to specify "SCHACHT'S."

SCHACHT'S LIQ. BISMUTHI SEDATIVUS.

Contains pure Bismuth and *Pepsina Liquida* in combination with sedatives—viz., in each drachm gr. 1-24 Morphia, min ij. Acid. Hydrocyan. (B.P.), and min. v. Tinct. Nucis Vom. A formula most serviceable in the treatment of gastric pain, nausea, and vomiting. In 4-oz., ½ lb., and 1 lb. bottles. Supplied without morphia when desired.

SCHACHT'S SYR. CINCHONÆ ALCOHOLICUS.

A standard preparation, of definite alkaloidal strength, containing the entire medicinal properties of the finest Cinchona Bark. It is, in fact, *Bark minus the woody fibre*, and its efficiency has been proved by careful medical inquiry. Dose: Ten to sixty drops.

SCHACHT'S PEPSINA LIQUIDA (Registered Title).

Fluid pepsine of extraordinary activity—tasteless, odourless, attractive to patients, and reasonable in price. Every teaspoonful when tested by the official B.P. process is *guaranteed* to effect the solution of **1000 grains AND MORE** of albumen, a weight equal to that of two hard-boiled eggs. Peptic power is the only test of value. Most of the fetid and repulsive dry Pepsines have proved worthless. In 4 oz. bottles, 2s. 6d. each; and larger sizes for dispensing at a cheaper rate. Dose: One drachm.

SCHACHT'S PEPSINA LIQ. c. BISMUTHO.

Each drachm contains in a concentrated form, besides the fluid pepsine, a full dose of Schacht's Liquor Bismuthi. An elegant and successful combination, Dose: One drachm. For dispensing, ½ and 1 lb. bottles.

N.B.—Peps. Liq. c. Bismutho Co. contains, in addition, 1 gr. of soluble Euonymin in each drachm.

SCHACHT'S PEPSINA LIQ. c. EUONYMIN.

Each drachm contains one grain of soluble Euonymin, and is a highly active and reliable digestive and hepatic stimulant. Dose: One drachm. For dispensing, ½ lb. and 1 lb. bottles.

SCHACHT'S LIQUOR CASCARÆ DULCIS.

A trustworthy and active form of Cascara Sagrada, from which the nauseous taste of that drug has been completely removed. Dose: One to three teaspoonfuls diluted. In 4-oz., ½ lb., and 1 lb. bottles.

SCHACHT'S LIQ. PODOPYHLLI c. BISMUTHO.

Has been prepared at the suggestion of an eminent Physician. The value of Podophyllin as an hepatic stimulant is unquestioned. Great uncertainty, however, attends its use when given in the solid form; but when administered in this perfect solution its action is sure and certain. Schacht's Liq. Podoph. contains a quarter of a grain in a drachm, and may be combined with other medicines as desired. Dose: ½ to 1 drm.

OF ALL LEADING WHOLESALE AND RETAIL HOUSES IN GREAT BRITAIN, INDIA, AND THE COLONIES. WHEN ORDERING, PLEASE SPECIFY "SCHACHT'S."

The Croonian Lectures

ON

THE MEANS BY WHICH THE TEMPERATURE OF THE BODY IS MAINTAINED IN HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on June 17th.

MR. PRESIDENT AND GENTLEMEN,—You will remember that in the last lecture we saw that it would be possible by taking simultaneous observations of the internal temperature, the surface temperature and the amount of sweat secreted, to find out in man whether a rise of internal temperature was due to a diminution in the loss of heat or an increase of the production. Further, it is clear that this method will enable us to tell the cause of the fall of a high temperature. The experiments that I am about to detail to you were carried out with these objects. The temperatures are all given in degrees Fahrenheit, and the amount of sweat in milligrammes.

A. *Temperature raised by a hot bath; experiments on myself* (see Table VIII.).

TABLE VIII.—*Temperature Raised by Hot Bath.*

Number of experiment.	Time.	Mouth temperature.	Abdominal surface temperature.	Milligrammes of sweat from abdomen in ten minutes.	Remarks.
	P.M.	Deg. F.	Deg. F.		
1	7.0	98·2	93·7	2·4	
	7.25	—	—	—	Got into hot bath (temperature 112°); remained in fourteen minutes. When I came out I felt faint, breathing deeply. The bath was then 108°. I rapidly dried myself, put on dressing-gown, and lay down.
	7.45	103·2	94·5	185·7	
	7.55	—	88·7	—	
	8.5	99·5	—	—	
	8.15	98·6	—	—	
	9.0	98·0	92·8	2·3	
2	3.30	98·2	92·8	1·5	
	3.40	—	—	—	Got into hot bath (temperature 112°).; remained in fourteen minutes. The bath was then 106°. Faintness and rapid breathing were not so marked. Dried as before.
	4.0	101·0	93·7	92·4	
	4.15	—	91·8	—	
	5.0	98·2	93·7	3·9	

The temperature rises in these experiments owing to the fact that the hot water stops the loss of bodily heat by radiation and conduction, and it prevents evaporation of sweat. Probably the hot water does not warm the body much in so short a time as the specific heat of the body is high. In both these experiments I could, by watching the skin, see that the secretion of sweat did not begin to be very profuse till a few minutes after I was out of the bath, but by ten minutes after it was extraordinarily abundant. It will be seen that in all respects the first bath produced more marked effects than the second; probably this was because the second cooled the faster. But both experiments teach that the evaporation of sweat is by far the most important agent in reducing the bodily temperature when it has been artificially raised by a bath, and it will be noticed that when such a large amount of sweat is secreted the surface temperature is lower than it was either before the experiment began, immediately after the bath, or some time after the experiment, when the secretion of sweat is nearly normal. This is no doubt due to the rapid evaporation of the sweat, and this means of reducing the temperature is so energetic that it actually makes the loss by radiation and conduction less, although the internal temperature is raised, and it will be seen that in the first experiment the surface temperature fell 5·8° in ten minutes, but in the second with much less sweat secreted it only fell 1·9° in fifteen minutes. Other striking facts are the rapidity with which a normal temperature is regained and the enormous quantity of sweat secreted.

B. *Temperature raised by Turkish bath; experiment on myself.*—Before the bath the mouth temperature was 98.8°, and the surface temperature of the abdomen was 90.5°. Milligrammes of sweat from the abdomen in 10 minutes 2 2. After taking these observations I went into the hot rooms and remained there an hour and twenty minutes, mostly at 120°, but for some time in rooms at 150° and 190°. Then I was massaged, shampooed, and had a shower bath. After which I was wiped quite dry, and then the mouth temperature was 99·8°, and the surface temperature of the abdomen was 92·3°. Milligrammes of sweat from the abdomen in ten minutes 46 1. Here, again, we see what a very energetic agent sweating is in reducing an artificially raised temperature, for after I had been sweating profusely for eighty minutes in the bath the sweat was still being secreted twenty times as fast as before the bath, but the quantity was not enough to make the surface temperature lower than before the bath.

C. *Temperature raised by damage to the brain.*—In two papers[2] I have shown that damage to the corpus striatum in rabbits raises their internal temperature. So many experimenters have confirmed this observation that I need not now trouble you with the details. The following table (Table IX.) shows the results I obtained in twenty-seven experiments.

TABLE IX.

Highest temperature after operation.	No. of degrees above that immediately before.	Highest temperature after operation.	No. of degrees above that immediately before.	Higiest temperature after operation.	No. of degrees above that immediately before.
Deg. F.	Deg. F.	Deg. F.	Deg. F.	Deg. F.	Deg. F.

105·8	4·8	104·2	2·0	—	—
105·6	4·4	104·2	1·2	—	—

In the last experiment the lesion was very extensive, and the fall of temperature was due to loss of blood. I show you a chart in which you can see very well the rise of temperature produced in a rabbit by damage to the corpus striatum (see Chart 1).

Many instances in which in man after a hæmorrhage into the corpus striatum the temperature has been raised have been recorded by Bourneville, Ferrier, J. H. Bryant, myself, and others, and references to these authors will be found in an address I gave at a meeting of the British Medical Association at Bristol in 1894.[3] These cases show that if

[1] Lecture I. was delivered on June 15th and published in THE LANCET of June 19th, 1897; Lecture III. was delivered on June 24th, and Lecture IV. will be delivered on June 29th.

after a hæmorrhage takes place into one corpus striatum the temperature is raised, it will be higher in the opposite or paralysed axilla than in the axilla on the non-paralysed side,

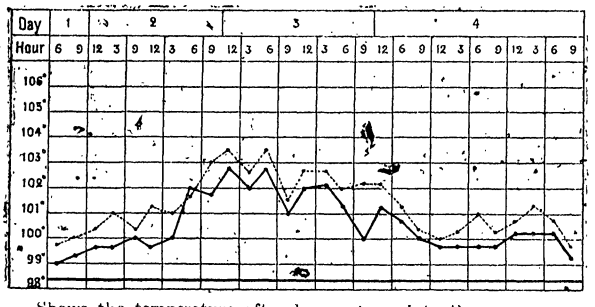

CHART 1.

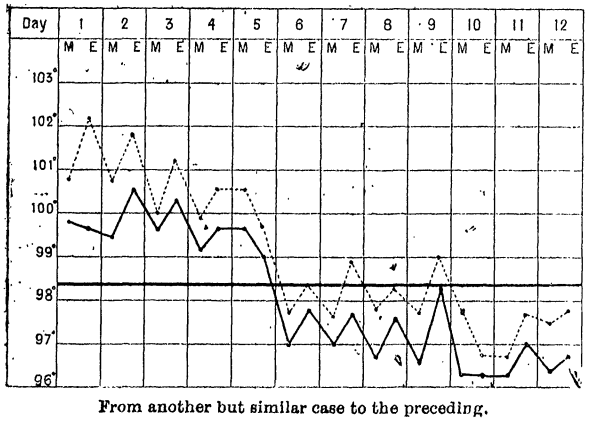
Shows the rise of temperature in a rabbit after damage to the corpus striatum.

and that the temperature on the paralysed side remains higher than that on the other even during the subnormal period which succeeds the rise. I have seen several cases which illustrate this, and I will show you charts of two of them (see Charts 2 and 3), and since I began to investigate

CHART 2.



Shows the temperature after hæmorrhage into the corpus striatum on one side. The dotted line shows that in the axilla on the side opposite to the hæmorrhage; the straight line that on the same side as the hæmorrhage. (From a patient in Mary ward.)

surface temperatures two more such cases have come under my care. They gave the following results (see Table X.).

It will be seen that in both these cases the temperature was always higher in the paralysed axilla—that is to say, the internal temperature was higher on the paralysed than on

CHART 3.

From another but similar case to the preceding.

the sound side. In the first case the surface temperature of the two arms was equal, but the amount of sweat secreted on the paralysed arm was much greater than on the other, therefore the loss of heat must have been more rapid on the paralysed side; but as in spite of this the internal temperature was raised, the quantity of heat in the paralysed arm must have been greater than that in the unparalysed arm. In the second case on one occasion the secretion of sweat was almost equal on the two arms and on two other occasions it was greater on the paralysed side. The surface temperature was always considerably greater on the paralysed arm, so that here the losses from evaporation, radiation and conduction are all greater from the arm with the higher internal temperature; therefore in this case, too, the quantity of heat must have been considerably greater in the paralysed arm than in the other. In neither case was there any visible dilatation of the vessels on the paralysed side, nor have I ever observed, even when the difference of temperature has been considerable, any dilatation of the vessels on the paralysed side in hemiplegia. This is evidence against the view that the increased temperature on the paralysed side is due simply to there being more blood in the paralysed arm, and when we remember that damage to the central nervous system, whether experimental or clinical (it is the commonest cause of hyperpyexia in man), frequently causes such a high temperature that we must suppose the production of heat to be increased, the observations I quote do lend strong support to the view that when in hemiplegia the temperature is raised in the paralysed axilla the increased quantity of heat in the paralysed arm is due to a greater production of heat in the paralysed than in the corresponding unparalysed limb. If this is so we have an instance in which a lesion that paralyses the motor function of muscle excites the thermogenetic, and thus we see that the functions are distinct.

D. *Temperature raised in fever.*—In any fever the general condition and temperature of different patients vary very much, and, therefore, single observations would be of little value. I have consequently made several observations on different patients in the following fevers, and if all the cases of any particular fever point in the same direction we shall probably be justified in drawing conclusions. I have always compared the observations made on a patient with a febrile temperature with those made on the same patient before he got up, but when his temperature was normal, or very nearly normal, unless his death prevented this.

I. *Typhoid fever* (see Table XI.).—The table shows that in all cases the amount of sweat secreted during the fever was small (from 2 to 3 milligrammes in ten minutes is the usual amount my boxes absorb from the abdomen of a healthy man) and less than when the temperature had fallen, therefore during the fever the loss of heat from evaporation was diminished. Also in every case except one the surface temperature rose less than the internal—in other words, the loss from radiation and conduction was not increased proportionately to the rise of internal temperature, and was therefore, relatively to the internal temperature, less during the fever. Thus, there is distinct evidence that in typhoid fever the loss of heat is relatively to the rise of temperature diminished, and this diminished loss no doubt helps to raise the internal temperature. Still, as the surface temperature always rose considerably, the actual loss by radiation and conduction must have increased during the fever, and probably the decreased secretion of sweat was not enough to counteract this. Therefore we may conclude that although certainly in typhoid fever the pyrexia is largely due to a lessened loss of heat, yet probably, too, the production is increased. Typhoid fever is remarkable in that, although it is a long-lasting disease with a high temperature, it has a low mortality; and these results suggest that one reason for this may be that the temperature is raised with the least expenditure of energy, for it is obviously more economical of energy to raise the temperature by diminishing the loss of heat than by increasing the production. Then, too, it is interesting to note that experience has shown that the best way to reduce pyrexia in typhoid fever is by sponging, that is by increasing the loss of heat. It is well known that the internal temperature of typhoid fever is irregular as convalescence approaches, and we see that the same is true of the surface temperature (see Case 5, high readings on 5th and 6th) and sweat (same case, reading on 5th). In Case 7 it will be noticed that as the patient got worse the surface temperature approached the internal—that is to say, he was dissipating energy the faster.

II. *Pneumonia* (See Table XII.). All these cases, except the first, show that the excessive sweating which is associated with the crisis lasts some days after it, and the fourth case shows how enormous the sweating of the crisis may be. This sweating must aid in keeping

Hosted by Google

down the temperature after the fever. In every case during the fever the secretion of sweat is less than when the temperature has fallen, but as then the secretion is still rather more than in healthy individuals and in typhoid fever patients whose temperature has fallen, probably the sweat secreted during fever is not much less than before the fever began. Therefore it appears that the diminution of the loss of heat owing to a dimunition in the amount of sweat secreted plays but a small part in raising the temperature. In only two cases did the surface temperature rise less than the internal, and in two it rose more (this explains the hot skin of pneumonia), therefore often in pneumonia the loss by radiation and conduction during the fever must be enormous. As, therefore, in pneumonia the loss of heat is so increased, the rise of temperature is for the most part due to an increased production of heat.

III. *Erysipelas* (see Table XIII.).—In both these cases the sweat was increased during the fever, and the surface temperature rose more than the internal temperature, so the dissipation of heat by evaporation, conduction, and radiation must have been very much increased. Consequently, the rise of temperature must have been entirely due to an increased production of heat, and not at all to a diminution of the loss.

IV. *Suppuration* (see Table XIV. A).—Here the considerable amount of sweat secreted after the abscess was opened and the temperature had fallen appears to show that sweating helped to keep the temperature down. In the first case at least the quantity secreted during the fever was so small that the raised internal temperature may have been partly due to a diminished loss of heat from lessened evaporation. In both cases, too, there was a diminished loss from radiation and conduction, for the rise of surface temperature was less than that of the internal temperature, in fact, on one occasion, the surface temperature was actually lower during the fever than when the internal temperature had fallen, and that although there was no excessive evaporation of sweat to bring it down. We may conclude that in these two cases of suppuration the raised internal temperature was, in part at least, due to a diminution in the loss of heat.

V. *Tubercle* (see Table XIV. AA).—I have made several

TABLE XIV. AA.—TUBERCLE.

8	Oct. 28th, 1896	101·4	97·8	3·6	4·0	General Tuberculosis.

observations on patients who were suffering from tubercle. Although the temperature fluctuates considerably they are always suffering from their disease, and therefore it is very difficult to obtain a normal standard. Consequently, I do not think the figures teach much about the process of this fever. You will notice, however, that the amount of sweat secreted is large even when the temperature is low, so that no doubt the increased secretion of sweat is often the cause of the fall of temperature. It is interesting to notice that, on the whole, the cases of general tuberculosis secreted less sweat than those of phthisis. In both forms of disease the surface temperature is, as a rule, low; this may be due to the large amount of sweat secreted. As the evaporation of this sweat must lead to a considerable loss of heat it is probable that in tubercle the production of heat is, as a rule, increased.

It appears from these observations that in some fevers the pyrexia is, in part at least, due to a diminished loss of heat, in others this is of but slight importance, and then the production of heat is very great; and this result goes to prove the truth of the suggestion I made earlier in these lectures—namely, that the processes which lead to a rise in temperature are different in different fevers. We have also incidentally learned much about the surface temperature and the secretion of sweat in the fevers we have considered.

Before leaving this subject I should like to draw your attention to some interesting figures obtained from a case of leucocythæmia. There was one white corpuscle to every ten red. The hæmoglobin was reduced to 17 per cent. of the normal, and the red corpuscles to 24 per cent. An observation gave the following result. The temperature of the mouth was 102·2°. The surface temperature at the umbilicus was 102·2°. The amount of sweat secreted in ten minutes was 1·2 milligramme. There are two points of interest here. First we have the high surface temperature with very little sweat; probably it would be impossible to have so high a surface temperature if there were much sweat, for the evaporation of the sweat would reduce it. Secondly, as the surface temperature was so high the loss by radiation and conduction must have been excessive, so the production must have been very high, and therefore even the small amount of hæmoglobin and the plasma carried between them enough oxygen for the metabolism necessary for this increased production. My best thanks are due to my house physicians, Dr. A. Salter and Mr. C. J. Harnett, for much help in these investigations. I have many observations on other fevers which I hope to publish subsequently.

Maragliano has published some observations which do not bear on the question of the production of heat, but they at any rate show that in some fevers the temperature depends very much upon the state of the cutaneous circulation—that is to say, upon the loss from radiation and conduction. He[4] applied the plethysmograph to the arm of fever patients after experiments on healthy men, and, in the fevers upon which he experimented, he found that as the temperature rose the volume of the arm diminished, and as the volume of the arm is chiefly dependent upon the flow of blood through the vessels of the skin, it follows that this was diminished; in other words, less heat was lost by radiation and conduction when the temperature rose. The table I show you gives the results obtained by observing a man suffering from malaria (see Table XIV. B).

TABLE XIV. B

Time.	Volume of arm.	Temp. (Deg. C.).
10.50	100	36·8
10.55	100	36·9
11.15	97	36·8
11.20	95	36·3
11.30	88	36·9
12.0	85	36·8
12.15	80	36·3
12.30	80	36·8
1.0	70	36·8
1.15	65	37·0
1.30	60	37·3 (slight shiver)
1.35	57	37·5
1.50	54	37·7
2.0	53	38·3
2.10	53	38·5
2.20	51	39·0
2.25	50	39·2
2.30	50	39·5
2.40	49	39·6

It will be observed that the contraction of the vessels preceded the rise of temperature. This is very strongly suggestive that it was the cause of it, and in the following table (I have only quoted the part of it which refers to the rise of the volume of the arm) (Table XIV. C) which gives results obtained from a young man suffering from ague, we also see that the vessels begin to dilate before the temperature begins to fall—a fact which also strongly suggests that the fall of temperature was due to the increased vascular cutaneous dilatation.

I should now like to refer to some observations which Dr. Archibald Garrod and I made upon each other with the object of finding out how healthy individuals varied their loss of heat under different circumstances. Table XV. shows the results of six pairs of observations made upon us, each pair being made at the same time. The first five pairs were all made after dinner in the evening. It will be

noticed that in these five pairs the temperature of the mouth of both of us was almost the same, but that four times out of the five my surface temperature was higher than his—on two occasions (the second and third) as much as 3·6° F. A possible explanation for the fact that on the fourth occasion my surface temperature was lower than his is that we made the observations in his house, which is about 200 yards from mine, and on the evening on which this observation was made I strolled to his house after dinner while there was a cold north-east wind blowing. On four out of the five occasions I sweated more than he did. The whole amount I perspired during the five observations was 15·3 milligrammes, but his

total amount was only 11·1, so that I perspired 38 per cent. more than he did. As, therefore, my surface temperature was higher and the amount of sweat that I secreted was greater I lost heat from radiation, conduction, and evaporation faster than he, and therefore my production per kilogramme was greater than his. We consequently learn that even healthy individuals vary much in their production and loss of heat. The last pair of observations is of little value, as the temperature of our baths was not the same. I have given in the table the temperature of the air, taken with both a wet and dry bulb thermometer. The air was driest on April 11th, on which day I sweated most, but this was not the day that Dr. Garrod sweated most; and on the next driest day I sweated less than on any other, so as far as these few observations go they do not show any relation between the humidity of the air and the amount of sweat secreted.

It is well known that muscular contraction is accompanied by a rise of temperature; therefore, were it not that the loss of heat is increased during exercise the temperature would always rise. In fact, often the increased loss does not compensate for the increased production, and so the temperature does rise. Many references to this subject are given by Pembrey.[5] Jurgensen found that the work involved in sawing wood for six hours raises the temperature of a healthy man 1·2° C. above normal. Davy showed that walking for two or three hours raised the temperature of the urine 0·8° C. Clifford Allbutt found that Alpine climbing raised the temperature of the mouth half a degree, and Liebermeister and Hoffman found their axillary temperature raised by the exertion both of coming up and going down a mountain. Hobday, too, has taken the rectal temperature of omnibus horses, and he finds that it is raised about 2° C. by hard work. Dr. Garrod and I thought, therefore, it would be of interest to make a series of observations on the effect of exercise on each other (see Tables XVI. and XVII.). It will be seen that a bicycle ride of seventeen miles in a high, dry, cold wind reduced the internal temperature of Dr. Garrod by 1·0, and my own by 0·8 of a degree I do not think this can have been due to the inhalation of cold air cooling the mouth, for we did not take the temperature of the mouth until we had been in the house for twenty minutes after the ride, and it must have been due to the rapid loss of heat caused by our going quickly through the high, dry, cold wind. With the exception of this bicycle ride it will be seen that exercise always raised Dr. Garrod's internal temperature and that mine was either unaltered or raised, but that mine was, on the whole, much less affected than his. There are other interesting points of contrast between us. Dr. Garrod's surface temperature was always considerably raised by exercise, while mine was usually slightly diminished. On the other hand, he sweated but little in comparison with me, for his average increased amount of sweat was 3·5 millligrammes, while mine was 7·05. The difference is really greater than this, for I took two bicycle rides in a cold, dry wind to his one, and in a very dry wind the sweat evaporates fast, and consequently not much is secreted when the observation is taken. Apparently, therefore, we are different in our methods of accommodating the loss of heat to the increased production due to the muscular exercise; he chiefly increased his radiating and conducting power; I chiefly increased my loss by evaporation. We have therefore a demonstrated proof that different people accommodate differently. These tables, too, show strikingly what Table XV. has already shown—namely, that when at rest my surface temperature is always higher than Dr. Garrod's, and that I perspire more than he does; in other words, I lose heat faster and therefore must produce more calories per kilogramme. As in fever, so here the data are not sufficient for us to say how many calories of heat the muscular exercise causes to be produced—we can only say that it must at least have been more than a certain number, for instance, my weight without my clothes is 61 kilogrammes; supposing the effect of exercise was to raise my temperature 0·5° C., and the loss by radiation, conduction, and evaporation were all increased, then I, as soon as when taking exercise I had raised my temperature the half a degree Centigrade, must have produced at least more than an additional 30·5 kilogramme Centigrade calories, as my specific heat is nearly that of water.

[5] Op. cit.

ON SOME SUPPURATIONS OF THE URINARY APPARATUS.[1]

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL; PRESIDENT OF THE MEDICAL SOCIETY OF LONDON.

I HAVE selected for consideration some points which seem to arise out of the pathology of certain suppurative processes as observed in the urinary organs in relation to the more modern treatment of surgical lesions and infections as generally practised. I shall first illustrate my observations by taking the most common, as well as the farthest reaching, cause of suppurations of the urinary organs, as occurring in the form of primary gonorrhœal infections in the male and the female, and as secondary developments in other parts of the genito-urinary system, as more frequently observed in the latter sex. The advances that have been made in connexion with the bacteriology of the urinary organs in reference to the kind and extent of these infections have already led to some useful applications in the way of treatment which I will briefly notice. The investigations of Guyon, Janet, Hallé, and others of the French school, more particularly as regards the life-history and cultivation of these micro-organisms, are of much interest and importance. It is, however, to the practical aspect of the subject that I shall confine my remarks. The first point that strikes one is that many of the cases spoken of as instances of chronic suppurative urethritis or gleet represent a far more extensive invasion than is generally supposed to be the case. In this lies, I have no doubt, an explanation of the difficulty that is not infrequently experienced in bringing cases of this kind to a successful and speedy termination. Many gleets are merely re-infections of the urethra from a bladder which serves the purpose of a medium for bacterial cultivation. So long as a gonorrhœa is confined to the area of the urethra as defined by that portion of the canal which lies in front of the compressor urethræ or "cut off" muscle,

[1] A paper read before the Medical Society of Brixton on June 10th, 1897.

Hosted by Google

the task of successfully combating the infecting suppuration is not usually a difficult one. The disease is within limits which can be readily acted upon by various agencies, administered either locally or by internal medication, and its course is generally limited both in severity and duration. When, however, these boundaries are exceeded and the bladder becomes invaded it is not easy to prevent re-infection taking place as if from an extraneous source. Hence the disease may be almost indefinitely protracted. Nor is invasion of the bladder in this way uncommon or necessarily indicated by acute symptoms such as would unmistakeably draw attention to the occurrence. In most instances of this the prostate is the only part of the urinary apparatus that may show any active indication of contact with the septic products, the mucous membrane of the bladder, though harbouring them, being singularly insensitive to bacterial influences. That infection occurs in this way can be readily demonstrated. When the bladder has been thus involved the conditions of the urinary organs, particularly during the night, are extremely favourable for bacterial cultivations, a circumstance which may explain the constancy and degree of matutinal suppuration exuded by the urethra which is a prominent symptom in this class of cases. It is rare, I believe, for gonorrhœal organisms to make their way up the ureters and to invade the kidneys—a fact which is no doubt due to the guarded manner in which these ducts enter the bladder and the constancy of the downward flow of the urine. That renal infection and urethral inflammation sufficient to cause a pyelitis of the former and a contraction or stricture of the latter can occur has been demonstrated as possible. Some years ago I examined the body of a middle-aged man who died from acute single pyelitis rapidly following upon a first attack of gonorrhœa. The ureter of the kidney involved was extremely dilated, a circumstance which was believed to be due to the patient having been in the habit for some years previously of passing renal calculi The opposite kidney was much congested. Mr. W. G. Nash[2] has recorded a case of strictured ureter which was probably caused in this way. In the female the widespread effects of the gonorrhœal infection are generally recognised.

The suspicion, however, that the bladder may be infected with micro-organisms should be made a matter of proof, and this can generally be done. For this purpose care should be taken to obtain a specimen of the urine as it exists in the bladder, minus any contaminations it may pick up in its transit along the urethra. The first portion of the urine passed should be rejected as probably containing the flushings of the canal, the balance being separately collected as representing the constituents of what may be called vesical urine. When it is possible a catheter specimen should be obtained, in accordance with the directions of the Clinical Research Association, where there are reasons for believing that the bladder is infected. In this way gonococci may be detected in vesical urine in cases of gonorrhœa. The mere fact that the urine is shown to contain bacteria does not necessarily imply that the individual is capable of inoculating another with gonorrhœa. Where, however, the gonococcus is discovered in the urine or the discharges of the patient, as is not unfrequently the case, I do not think there can be any doubt as to the possibility of its communication to some one else. The bacteriological examination of these secretions may furnish important evidence in determining whether a person who has been comparatively recently infected should be allowed to marry. So long as these conveyers of infection can be detected in the urine or the discharges, so long may we expect that transference of the disease is liable to follow. In these cases of secondary infection of the bladder, caused by extension from the urethra, I have for some time placed much reliance upon the irrigation of the bladder and urethra with antiseptics, as described by Dr. Janet,[3] with some modifications. The object is attained in the following manner. The apparatus consists of an ordinary hydrostatic bladder tank, holding about one pint of water and fitted with a nozzle to which a No. 8 Jacques' rubber catheter can be attached. The tank is elevated about six feet from the ground, and is filled with warm water containing 30 minims of Condy's fluid to a pint of the latter. For lubricating the catheter I use carbolised vaseline. The patient having emptied his bladder spontaneously is placed in the recumbent position and the catheter is then passed. Before the nozzle of the irrigator is connected with the catheter as it lies in the bladder the fluid is allowed to run off for a few seconds so as to ensure that there is no free air in the tube of the apparatus. Then the connexion is made and the fluid is allowed to flow into the bladder by degrees until the patient is conscious of feeling distention. I generally use from twelve to sixteen ounces for this purpose, allowing it to enter the bladder in jets of about three or four ounces at a time. In this way the feeling of any sudden or extreme fulness is avoided, and the entire area of the mucous membrane of the bladder is unfolded and opened out, and thus comes in contact with the permanganate solution. When a sufficient degree of bladder distension is obtained the catheter is slowly removed, care being taken not to allow the fluid to escape. I then usually lightly palpate the bladder above the pubes with the hand before the patient stands up. This he should then do and proceed to empty his bladder of its contents by his natural efforts. Thus not only is the bladder washed out, but the whole urethra is flushed in a manner that is impossible by any other artificial method. As the patient is voiding the contents of his bladder it is well to direct him to suddenly interrupt the outflow once or twice by pressure with the finger on the penile urethra. In this way the lacunæ of the canal are also distended and flushed by the irrigating fluid. This completes the process, which may be repeated once or twice in the twenty-four hours, until the urine and the urethral mucus are found free from organisms. Most patients after proper instruction will be able to carry out all these details. On the conclusion of each irrigation the patient should rest for a time in the recumbent position. I have only referred to the permanganate of potash in great dilution as the flushing agent for use in these cases. Half a drachm of Condy's solution, as I have already mentioned, gradually increased to a drachm in a pint of water, has given me good results. In other instances the preparation known as "Sanitas," in the proportion of an ounce to a pint of water, has also answered equally well. Neutral sulphate of quinine (1 grain to the ounce) may also be used. More rarely I have employed nitrate of silver (one-sixteenth grain to the ounce) and perchloride of mercury. The last sometimes produces a good deal of pain, though only used in the proportion of 1 in 10,000. I have no doubt for aborting infections the perchloride is the most effective. When used for the latter purpose in the proportion of 1 in 10,000, and after the solution has been spontaneously voided from the bladder as in the act of micturition, the bladder may be filled with a strained solution of albumin—say, that yielded by one fresh egg—in a pint of tepid or nearly cold water. If this is done and the albuminoid solution voided in like manner from the bladder, any pain, smarting, or spasm that the perchloride solution produced at once ceases. Similarly, a weak solution of chloride of sodium, injected into the bladder after a solution of nitrate of silver has been used for this purpose, not only removes any irritation the latter may provoke, but coats over the inflamed mucous membrane with a thin layer of chloride of silver, which often affords much relief when cystitis is present. Probably there is no better bactericide than nitrate of silver in these cases, but it requires to be used with the precautions mentioned when good results may be obtained. In this class of cases where suppuration proceeds directly from infection the internal administration of bactericides may be advantageously combined with the local treatment just referred to. In rendering the urine sterile and destructive to the life of the gonococcus there are no more effectual agencies than some of those which are derived from the vegetable kingdom. I refer particularly to the volatile oils which are so largely eliminated by the kidneys of which I may instance sandal wood, copaiba, cubebs, and similar drugs. By these it is possible to so saturate the urine as to render the existence of certain forms of bacteria impossible. I shall, however, refer later to other methods of sterilising the urine which may also be utilised in the treatment of infecting forms of urethritis and cystitis.

I will now notice other varieties of urinary suppurations which may be best illustrated by certain cases of prostatic obstruction. Though the urine is in these instances usually purulent and charged with bacteria the latter are not infective in the same sense as those I have previously referred to in connexion with a specific form of urinary suppuration. On the other hand, it must be remembered that these micro-organisms are readily capable of transference from one individual to another through the medium of catheters and

[2] Brit. Med. Jour., April 8th, 1893.
[3] Journal des Maladies Génito-Urinaires, Paris, 1896.

Hosted by Google

instruments of this kind, and thus they may be regarded as factors in the causation of extensive and far-reaching suppurations in these parts. The principles of treatment in this class of suppurations are the same as those I have already mentioned, subject to certain modifications which I will proceed to notice. Putting aside the consideration of the precise means which these cases often require for mechanically emptying the bladder and thus preventing decomposition of the urine taking place, the restoration of the secretion to its normal state will be mainly brought about by antiseptics in the manner indicated. The more or less atonic condition of the bladder in these obstructive cases seldom permits us to employ the process of auto-irrigation as previously described, and we must therefore for this purpose avail ourselves of one or other of the methods usually practised. In offering a few remarks on the toilette of the bladder I will do so in reference—(1) to the disposition of the parts requiring ablution; (2) to the mechanism employed; and (3) to the composition of the cleansing fluid. Most of us, I think, will admit that we are disposed to draw our ideas relative to the process of washing out the bladder from the natural state of the parts such as we see in anatomical plates. If, however, we select for our guidance the majority of pathological specimens illustrating the obstructive diseases of these parts we shall at once recognise the difficulties that beset us in our endeavour to wash out these, as we should do, for instance, in the case of a pint vessel. Take, for example, the hypertrophied bladders, with their various saccules, pouches, and dependencies, which are met with in connexion with advanced urethral stricture in younger adults and in persons of more advanced age who are the subjects of obstructive prostatic disease. In many of these the bladder is no more like the natural organ than the interior of a glass bowl resembles the section of a coarse bath sponge. The contents of the latter you could hardly ever hope to wash out effectually, though you may succeed in soaking them out. For washing out the bladder I almost invariably employ the hydrostatic tank which is now so generally used. It has, I believe, many advantages over syringes which I need not here stop to enumerate. When the bladder is much fasciculated it should be done in the recumbent position, with the object of opening out the mucous membrane as completely as possible without causing pain, the object being to reach irregularities on the surface which otherwise would escape contact with the lotion. When the bladder is much pouched it is a good plan, after filling it and before removing the fluid, to cause the patient to agitate his body from side to side so as to bring any dependencies there may be within reach of the antiseptic. In various ways such as these the process of washing out the bladder may be rendered more searching. For washing out in ordinary cases of bacterial urine I usually prefer boracic acid or the boroglyceride. Condy's fluid, sanitas, and iodoform may also be similarly employed. As I have already said, a solution of nitrate of silver in the proportion of $\frac{1}{16}$ of a grain to the ounce is often efficacious in rendering turbid urine clear after other things have failed. The sterilisation of the urine by internal medicines is an important adjunct in the treatment of the class of cases I am now referring to. It is quite unnecessary to draw attention to the many obvious ways in which the urine may thus be altered. The specific gravity, the reaction, and the composition of this secretion may to a large extent be artificially influenced, and in these directions the course of suppurative diseases of the urine passages may be importantly and favourably acted upon. And this brings me to speak of some of the means at our disposal for rendering the urine sterile so far as the most important factors in suppurative diseases are concerned. I have already referred to the sterilising influence that certain oils and essences, such as sandal wood and copaiba, are capable of exercising in this way. No less marked is the effect that boracic acid taken internally is capable of effecting in controlling bacterial life in the urine. Probably no better proof of this exists than in the results observed in connexion with operations on the urethra, such as the passing of catheters and in internal urethrotomy. The late Dr. Palmer, of Louisville, showed many years ago that by the use of boracic acid beforehand the development of urethral rigors and fever, under these circumstances, was rendered highly improbable, and this has since been amply proved to be the case. Similarly the use of quinine as a prophylactic against urine fever has been shown to be most efficacious; salol and other like drugs are also well recognised as urine sterilisers. Though boracic acid in doses of from ten to fifteen grains three or four times in the day is probably one of the most reliable sterilisers, it so often disagrees and causes dyspepsia as to interfere greatly with its use for the purpose. Some years ago my attention was called to a preparation called boro-citrate of magnesia, which was described by Dr. Koehler, of Kosten,[4] in Germany, as a solvent for uric acid calculi, and gravel. In the communication referred to it is stated that it is prepared by dissolving boracite, a natural borate of magnesia which is found in Stassfurt, in citric acid. Whether it is actually a solvent for uric acid I am not prepared to say. Whilst testing it for this purpose I found that it frequently had a remarkable effect in sterilising and clearing up purulent urine and in favouring the expulsion of calculi and gravel by its flushing effects on the urine passages. For the latter purpose I have used it for the last ten years in conjunction with other means for preventing urine decomposition with considerable effect. I am in the habit of prescribing it in teaspoonful doses in half a tumbler or so of either warm or cold water two or three times in the day. It is extremely palatable to take and readily dissolves. We have other means for sterilising the urine by the mouth which I will mention, as one method or one drug is not universally applicable. There is a combination of the salicylate of soda with the benzoate of soda which possesses this power in a marked degree. I have frequently found urine which has been rendered opaque by the presence of pus and was swarming with bacteria rendered clear in the course of a few days after the use of this preparation. I usually prescribe fifteen grains of both of these salts to be taken together three times a day in an ounce of chloroform water. The hyposulphite of soda in half-drachm doses has also in some instances effected the same object. The principle of urine sterilisation may, however, be extended to other purulent or bacterial conditions of the urinary apparatus. I refer more particularly to some of those chronic suppurations resulting from the formation of abscesses in connexion with the prostate and prostatic urethra, where the pus was originally discharged, sometimes against gravity, into the latter canal. These are often most difficult to heal by reason of the absence of a free and dependent opening. Yet, on the other hand, the opening of the perineum and the incising of the prostate to secure free drainage of the discharge is a proceeding that cannot always be undertaken without some degree of risk in elderly subjects. The thorough cleansing of these deep parts by the use of antiseptics in the form of auto-irrigation, as described in the earlier part of this paper, will be found efficacious in many of these cases of chronic suppuration. In some instances of prostatic suppuration it is almost impossible to flush a sinus connected with this part so long as a catheter of any kind is retained in the bladder. On the other hand, this object may be often readily effected by the spontaneous contraction of a bladder more or less distended with fluid. In the sinuses, for instance, arising out of tuberculous prostatitis this method usually proves very effectual. Again, I have resorted to this way of flushing urinary fistulæ with some antiseptic fluid when the primary cause of them has been removed, as by gradual dilatation or after internal urethrotomy. Tortuous routes through the perineum may, by washing out through the medium of the bladder two or three times if necessary in the twenty-four hours, be thus healed. A few months ago I saw a middle-aged man with a tight stricture in the deep urethra which only admitted a No. 4 bougie. In addition there were two chronic perineal fistulæ—one opening in the left buttock and the other by the side of the scrotum, through which almost the whole of the urine was passed at the time of micturition. The patient's condition was an extremely distressing one, as it was impossible for him to pass urine with any degree of comfort except upon a water closet. I divided the stricture from within by Maisonneuve's urethrotome. A catheter was then tied in the bladder for forty-eight hours, and on its removal a No. 12 silk catheter à boule was introduced morning and evening. After washing out by means of this in the ordinary way the bladder was finally filled with about a pint of warm boracic lotion, which the patient was required to void naturally in the standing position on the catheter being withdrawn. The fluid escaped as in the ordinary act of micturition with this patient—namely, partly by the urethra and partly through the false routes. The proportion of the fluid coming through the

[4] Berliner Klinische Wochenschrift, Nov. 3rd, 1879.

Hosted by Google

urethra gradually increased, whilst that passing through the two fistulæ grew less daily, and in the course of ten days entirely ceased. This method of procedure I have found from repeated trials to importantly contribute in promoting the sound healing of these sinuses and the comfort and cleanliness of the patient.

I have thus endeavoured to bring under notice, as briefly as possible, some ways of influencing urine in connexion with certain specific and non-specific suppurations of the urinary organs, from the kidneys downwards.

BY J. DIXON MANN, M.D. ST. AND., F.R.C.P. LOND,

PHYSICIAN TO THE SALFORD ROYAL HOSPITAL; PROFESSOR OF FORENSIC MEDICINE IN OWENS COLLEGE; EXAMINER IN FORENSIC MEDICINE IN THE UNIVERSITY OF LONDON AND IN THE VICTORIA UNIVERSITY.

SUDDEN death from natural causes, especially when it occurs under suspicious circumstances, is not infrequently the subject of medico-legal investigation. It is, therefore, necessary that medical practitioners should be familiar with the conditions under which sudden death is usually encountered, since the investigation of cases of this kind—often intrinsically difficult—may, in the absence of some previous knowledge of the subject, prove extremely perplexing.

Cases of sudden death from natural causes may be classified under three heads: (1) deaths which are due to the presence of a disease which is universally recognised as one liable to suddenly terminate fatally—for the most part such cases yield satisfactory post-mortem evidence as to the cause of death; (2) deaths due to the presence of a disease which, when fatal, does not usually end life abruptly, and which, consequently, is not generally regarded as a cause of sudden death—in such cases post-mortem examination frequently yields inferential rather than conclusive evidence as to the cause of death; and (3) deaths which do not result from any ascertainable disease, and as to which consequently no evidence whatever is afforded by post-mortem examination.

1. Roughly speaking, about one-half of the total number of cases of sudden death from natural causes in adults is, more or less, due to heart disease, which has existed for some time, and in which no furthur change is in progress at the time of death—such as valvular disease, angina, fatty heart, and sclerosis of the cardiac muscle from chronic myocarditis. In many cases concurrent lung or kidney disease complicates the statistics, such cases frequently being tabulated as deaths solely due to heart disease. Spontaneous rupture of the heart, mostly in men, may exceptionally occur; the left ventricle, often towards the front, is almost invariably the seat of the rupture. It is to be remembered that in traumatic rupture of the heart the right side, usually the auricle, suffers more frequently than the left in the proportion of about as 70 is to 54. Apoplexy and other cognate brain lesions rank second as natural causes of sudden death. It is to be noted that miliary aneurysms of the vessels of the brain, although most common in persons past middle life, occasionally occur in young people, even in children, and by bursting cause death from apoplexy. Chronic alcoholism, a potent factor among the causes of sudden death, is frequently associated with rapidly terminating heart and brain disease. Asphyxia, a not unfrequent cause, may be due to œdema of the glottis, membranous deposit in the trachea, pressure of a neoplasm on the trachea, spasm of the vocal cords, pulmonary embolism, air embolism rupture of a vessel or of an aneurysm into the air-passages, asthma, whooping-cough, pneumo- and hæmo-thorax, pleuritic effusion, and epilepsy. The rupture of a gastric or of an intestinal ulcer, of an aneurysm, of a varicose vein, of the surroundings of an ectopic gestation, the formation of a peri-uterine hæmatocele, may severally prove quickly fatal. Nephritis (uræmia and apoplexy), diabetes, exophthalmic goitre, and Addison's disease may also terminate with unexpected rapidity. Hæmorrhage into the pancreas occasionally causes sudden death, apparently from the impression produced on the contiguous nerve centres. It is most common in males over forty years of age, who may up to the occurrence of the hæmorrhage to all appearance be in perfect health. Obesity, the habitual use of alcohol, and the presence of heart disease appear in many of the cases to be predisposing causes. Koetschau,[1] however, observed hæmorrhage into the pancreas in a woman—an alcoholic—in her twenty-fourth year. Occasionally it occurs in spare people who are free from obvious disease and who are abstemious as regards alcohol. The sufferer may die within half an hour after the occurrence of the hæmorrhage or he may survive for twenty-four or even thirty-six hours. Draper[2] records five cases between the ages of twenty-six and fifty-five years, of which three were men and two women. Fitz[3] tabulated sixteen cases, of which eleven were males between thirty-one and seventy years of age, and five were females between twenty-six and forty-seven years. Sudden death has in several instances followed spontaneous rupture of an enlarged spleen, the result of tropical malarial influences, the individual immediately before rupture being to all intents and purposes quite well. Pellereaux[4] gives the history of thirteen cases of rupture of the enlarged spleen; in five the rupture was spontaneous, and in the remainder it was due to apparently inadequate causes, such as a simple fall in the street. It is to be borne in mind that when the spleen is thus enlarged a mere pat with the palm of the hand may determine rupture and consequent speedy death, which, in the absence of a knowledge of the experience of others, might readily be assumed to be the result of criminal violence.

It is to be remembered that some of the above-named diseases may exist without giving rise to any symptoms until the fatal moment arrives; this applies with special force to diseases which have a prolonged course, during which, as a rule, symptoms indicative of the disease declare themselves. Such a disease is gastric ulcer. I have seen more than one case in which, until the fatal rupture occurred, absolutely no symptoms were experienced, not even such as might have been attributed to simple dyspepsia; in one such instance a second ulcer was present in the walls of the stomach in addition to the one that ruptured and caused death, and yet until perforation occurred the patient never felt in the stomach any abnormal sensation whatever. As regards some of these diseases, such as spasm of the vocal cords, whooping-cough, and asthma, the most careful post-mortem examination may fail to determine the cause of death. Epilepsy may or may not leave characteristic appearances, such as recent injury to the tongue, ecchymoses of the conjunctiva, the face, the neck, and occasionally of the trunk, together with froth (possibly blood-stained) on the lips. Lesser[5] examined seventeen cases of death from epilepsy and found that the tongue had been bitten in eight, and that in six conjunctival or subcutaneous hæmorrhages on the face, breast, or trunk were present.

2. *Certain diseases which, when fatal, do not usually end suddenly may exceptionally do so.*—Such are abscesses and tumours of the brain, meningitis, diphtheria, tracheitis, enlarged thyroid, pulmonary apoplexy, pneumonia, phthisis, pneumo-thorax, pleurisy, ulcerative endocarditis, old adherent pericardium, pericarditis, volvulus, and other causes of acute intestinal obstruction, peritonitis, gall-stone colic, rupture of an echinococcus in the liver or elsewhere, Bright's disease, influenza, gout, and acute rheumatism. When fully developed several of these diseases are usually inhibitive of locomotion, but they occasionally occur in a latent or an ambulatory form and terminate suddenly without their presence being even suspected; it is no uncommon event for a man suffering from such a disease to walk unaided into the out-patient department of a hospital and even to die suddenly ere treatment can be adopted. Meningitis may be latent and may lead to sudden death; even pus may be present without giving rise to any symptoms until immediately before death. Ollivier[6] records the case of a man who was taken ill while at work. He went to bed and died in four hours, and at the necropsy the cause of death was found to be purulent meningitis. Death may suddenly attack a person (especially in childhood) who has middle-ear disease, death

being due to septic meningitis or to the formation of an abscess in the sphenoidal lobe or in the cerebellum. Slow-growing cerebral or cerebellar tumours not unfrequently cause unexpected and rapid death. Rapidly developing œdema of the larynx may exceptionally cause sudden death in adults as well as in children. A man, aged twenty-eight years, who was under treatment for an ordinary sore-throat, one day suddenly grasped his throat with his hands, ran round the room, and expired in two or three minutes. At the necropsy œdema of the larynx, along with signs of death from asphyxia, were found. The advance of an acute disease towards a fatal issue may be extremely rapid. Strassmann[7] examined the bodies of two young women who went to bed not feeling quite well, although they had done their work during the day; the following morning they were found dead in bed, and the necropsy showed that death was due to diphtheritic deposit which had travelled rapidly down the bronchi. Diphtheria may cause unexpected death during the stage of convalescence. Ransom[8] saw a girl, aged fourteen years, who was rapidly recovering from the effects of diphtheria when she died quite suddenly on the eighteenth day. It is extremely important to remember that diphtheritic paralysis, which may be suddenly fatal from heart failure, is by no means uncommon after *a latent attack of diphtheria that has escaped notice;* this holds good when the disease attacks other parts than the fauces. Guthrie[9] saw a girl, aged two years, with diphtheritic vulvitis, who died very suddenly from cardiac failure. In addition to the neuritis, which is liable to affect the innervation of the heart, a clot may form in the right ventricle after an attack of diphtheria and may cause sudden death. When an enlarged thyroid causes sudden death the gland is usually very considerably hypertrophied; sometimes hæmorrhage takes place into a cyst and determines speedy suffocation from increase of pressure which was previously all but sufficient to provoke fatal dyspnœa.

In addition to ordinary pathological conditions which may lead to rapid occlusion of the air-passages, and consequently to sudden death, one or two exceptional causes may be mentioned. Vedi[10] records the case of a man in the first stage of general paralysis who was getting out of bed, when he cried out that he felt ill. He at once became unconscious and died immediately. At the necropsy a round worm (ascaris lumbricoides) six inches long was found in the left bronchus, the characteristic signs of death from asphyxia being present. In a few instances the unsuspected presence of a laryngeal polypus has caused sudden asphyxial death. In young children and in profoundly intoxicated individuals regurgitation of the contents of the stomach into the mouth, with subsequent aspiration of a portion of them into the air passages, is a not unfrequent cause of sudden death; this accident, however, may happen to adults who are not intoxicated. Coutagne[11] relates the case of a woman, aged forty-four years, who whilst walking in the street felt unwell and went into a druggist's shop. She vomited on entering, became cyanosed, and straightway died. A necropsy revealed an enormously dilated stomach containing more than two quarts of semi-fluid food, some of which had found its way into the mouth and nasal passages; the bronchi were completely obstructed with it. Corvisart one evening paid a surprise visit to his clinic. The concierge, who had been dining too well, felt that he was caught, and the emotion caused him to feel sick; he made a violent effort to avoid vomiting and fell down dead. At the necropsy the trachea and bronchi were found full of partially digested food. It is noteworthy that in some cases of death thus caused, especially when occurring in elderly people, death takes place with exceeding rapidity and appears to be due to syncope, the post-mortem signs of death from asphyxia being entirely absent. Pleurisy and old pleuritic adhesions may cause sudden death; pleurisy with effusion may exist (without materially interfering with the breathing) in a man who is going about as usual, who, after slight exertion or trifling violence, or even in the absence of both, may die instantaneously. Brouardel[12] mentions the case of a police officer who, on receiving a blow on the chest from the fist of a man whom he was arresting, fell down dead. At the necropsy the right pleural cavity was found full of fluid, and no other indications as to the cause of death were present. In children the existence of pleuritic effusion, apart from violence in any form, is liable to cause sudden death; in adults also, especially on change of posture—as on getting up after some days' confinement to bed—there is in pleuritic effusion great risk of immediate death; the passage of an aspirating-needle into the pleural cavity has occasioned death either immediately or after an interval of several hours. Latent pneumonia is not unfrequently suddenly fatal in old people, the individual apparently being in his usual health up to the time of his death; in such cases nothing is discovered on post-mortem examination beyond the anatomical changes usually produced by the disease when it has run its ordinary course. Latent pneumonia may also be suddenly fatal in the young. Ollivier[13] records the case of a young woman, aged twenty-two years, who did not feel well, but she dressed herself to go out, and shortly after was found dead; the necropsy revealed double pleuro-pneumonia as the cause of death. Death from latent pneumonia may be exceedingly sudden. Strassmann[14] records the case of a man, aged fifty years, who called at a registry office in order to obtain employment; whilst the clerk was referring to the register the applicant fell down dead, and at the necropsy the whole of the upper lobe of the right lung was found to be in a state of grey hepatisation. Associated with intoxication pneumonia may cause sudden death in the young as well as in the aged. A man, aged twenty-four years, was locked up for being drunk and incapable; the next morning he was found dead in the cell, and the necropsy revealed complete consolidation of the left lung with commencing mischief at the base of the right.

In some diseases which occasionally terminate suddenly the issue may be determined by an overloaded stomach. Sturges and Wilkins[15] record the case of a boy, aged seven years, apparently in good health, who ate a hearty dinner and immediately after played cricket for an hour and a half. He then ran to school, suddenly fell down insensible, and died forthwith. At the necropsy signs of recent pericarditis, with soft adhesions, were discovered, all the organs except the heart being healthy. Under the strain of violent exercise the overloaded stomach impeded the diseased heart to such an extent as to suddenly arrest its action. In a large number of the cases in which death suddenly occurs the victim was undergoing some exceptional form of physical exertion at the time, such as playing a fatiguing game, hastening to catch a train, mounting stairs, defecating, or was engaged in sexual intercourse. Sudden death from acute intestinal obstruction is well illustrated by a case recorded by Rake.[16] A strong man, aged fifty years, when gardening, was suddenly attacked with vomiting and pain in the abdomen. He died in two hours, and at the necropsy a volvulus of the transverse colon was found. Possibly death was due to disturbance of the solar plexus. Rupture of the gall-bladder is an unusual cause of sudden death, but instances of it are on record. In one such a man suddenly experienced a severe pain in the abdomen, he became collapsed and quickly died; on post-mortem examination the gall-bladder was found to be ruptured, and from it a number of gall-stones had escaped into the peritoneal cavity. Bright's disease, both acute and chronic, occasionally causes sudden death without any indications of uræmia or of apoplexy. Debove and Capitan[17] relate two cases of interstitial nephritis, the patients enjoying good health up to the moment of death, which occurred suddenly from syncope, and which was not preceded by any morbid phenomena; no trace of valvular lesion was found after death in either case, but there was some sclerosis of the heart muscle. In advanced contracting kidney with concurrent hypertrophy of the left ventricle sudden death may take place without any post-mortem indications as to the ultimate cause of death either in the brain or elsewhere. It is to be borne in mind that patients with gouty kidney and high arterial tension may die suddenly from rupture of a vessel elsewhere than in the head. I have seen two such cases in which a cardiac vessel ruptured, death occurring very rapidly from accumulation of blood in the pericardium.

Rapid death from the rupture of a typhoid ulcer is, unfortunately, a too common occurrence in the case of patients under treatment for that disease; occasionally it happens in a case of the ambulatory type. A strong man

who was returning home from his day's work in the evening suddenly died; the cause of death was found to be rupture of an enteric ulcer of the ileum. Sudden death from enterica, however, is not always caused by rupture of an intestinal ulcer; in exceptional cases death appears to be due to rapid or instantaneous heart failure, occurring most frequently about the beginning of the third week. Dieulafoy[18] found that the fatal period most frequently occurs from the seventeenth to the twenty-fourth day of the disease, the largest number of deaths occurring on the nineteenth, twentieth, and twenty-first days, and that sudden death is not unfrequent in mild cases; he instances the case of a young woman, aged eighteen years, who, on the seventeenth day of the fever, whilst conversing with a nurse, was seized with convulsive movements of the face, became pallid, and died immediately. In such cases microscopic examination of the heart muscle does not show that it has undergone fatty or other changes. Marvaud[19] describes two forms of unexpected death from typhoid fever—one from syncope, in which death is instantaneous; the other from embolism of the pulmonary artery, in which, though sudden, death is not instantaneous. He records several instances, the earliest occurring on the thirteenth day of the fever, and the latest, which is distinctly exceptional, on the thirty-ninth day. Statistics collected by Dewèvre[20] indicate that sudden death from typhoid fever reaches its maximum between the ages of twenty and twenty-five years, and that it is commoner in men than in women. In children sudden death may occur in the early stage of typhoid fever, just when the intestinal follicles are beginning to swell.

Instances have occurred of sudden death due to heart-failure following an attack of influenza; post mortem, the heart has been found soft and flabby. Occasionally sudden death occurs in elderly people afflicted with gout, and also in those who are excessively corpulent, in some instances without affording any post-mortem evidence as to the actual cause of death. Kisch[21] records nineteen cases of sudden death in obese persons—twelve from acute œdema of the lungs, six from cerebral hæmorrhage, and one from rupture of the heart. Seven were under fifty years of age, and eleven were above fifty. Fifteen were men and four were women.

Acute rheumatism may end in unexpected and sudden death. Priestley[22] states that a woman, aged twenty-seven years, whilst in the early stage of rheumatic fever of a mild type without heart complication, suddenly lost the pain in the joints, went to sleep, and soon after was found comatose and she died. Bristowe[23] relates two cases of acute rheumatism in young women which ended suddenly in fatal syncope. Allbutt[24] records a case in which rapid and unexpected death during an attack of acute rheumatism was due to œdema of the glottis.

3. In most of the cases in which death suddenly takes place without any cause being revealed on post-mortem examination, it is determined by some external causal influence either acting directly on the nervous system or mediately on it by means of a very slight and apparently totally inadequate physical impact; therefore, in relation to this group, the term "death from natural causes" includes death arising from external and possibly abnormal influences, which, however, cannot be regarded as being essentially lethal. Several instances are on record in which death suddenly occurred to an individual who was in a state of extreme mental excitement without the intervention of any physical cause whatever. Templeman[25] examined the body of a man who, ten minutes after a violent scene with a drunken son, no blows being struck on either side, was found dead. At the necropsy the cardiac valves and the coronary arteries were found to be free from disease, and the muscular substance of the heart was free from fatty changes, being to all appearances perfectly healthy; no lesion was found that would account for death. Maschka[26] relates that two women were in the midst of a furious verbal encounter when one of them seized a broom and made as though she would strike the other; without any blow being delivered the woman who was menaced fell down dead. No abnormal condition was found at the necropsy. Marchal[27] received a military prisoner under his care in the hospital; the man had a profound dread of being sent back to prison, and as the medical officer was reading the memorandum of his previous behaviour the prisoner was observed to be greatly perturbed and suddenly fell back dead. At the necropsy no lesion except engorgement of the cerebral meninges was found to account for death. The inferential diagnosis of "heart disease," which is so satisfying to the public and also to many medical practitioners would have been accepted, in the absence of post-mortem examination, as being entirely fitted to these cases; a distinction is to be drawn, however, between death due to disease of the heart and death due to profound perturbation of the nerve centres causing inhibition of a heart in which there is no trace of disease. When searching after death for evidence of disease in a suspected heart it is to be noted that absence of atheroma or of narrowing of the mouths of the coronary arteries is not sufficient to exclude angina as a cause of death; it is necessary to lay open the entire length of the coronary arteries, since the seat of obstruction may be some distance down the artery, the orifice itself being quite patent. In the three cases just narrated there was absolutely no physical injury or impact even of the most trivial kind; death appears to have been due to cardiac inhibition caused by intense mental emotion. Such cases serve to explain those in which death follows a slight injury or physical impact that in itself is a totally inadequate cause of death, but which, when coincident with a climax of expectancy occurring during a period of acute apprehension or of extreme terror, may suddenly and completely inhibit, or in some instances profoundly depress, the heart's action; in the latter case death may not take place until several hours after the occurrence of the causal event, as in the following instance related by Beaunis.[28] A man whilst shooting wild beasts was pounced on by a panther. Some Arabs who were present immediately shot the animal, and on examining the victim found that the panther's claws had only inflicted on the shoulder a few pricks so slight that they scarcely bled; the man remained in a state of profound terror and died on the following day. At the necropsy no lesion was found to account for death; all the organs were healthy and the claw-marks were quite superficial. Another and still more remarkable case which occurred in India is recorded by Francis.[29] A man was roused out of sleep by feeling something creeping over his naked legs. Having an innate and intense dread of reptiles, and imagining that it was a cobra, he became collapsed and died in six hours, although before death took place it was discovered that a harmless lizard had been the cause of his fright; the patient, however, was too profoundly collapsed to recover. The immediately lethal effect literally of a mere touch is well illustrated by an instance which occurred to Dupuytren, who, when about to perform lithotomy on a boy, demonstrated to his students the line of the projected incision by drawing his finger-nail along the skin of the perineum; the boy immediately fell back dead. Nussbaum[30] states that as a surgeon examined with a sound the bladder of a robust peasant woman she closed her eyes and died forthwith. Cazenave[31] relates that a man, aged sixty years, was about to undergo lithotomy, and when the surgeon introduced the sound into the urethra the patient suddenly turned pale, lost consciousness, and died in ten minutes. A woman desired to be placed under the influence of chloroform before having a tooth drawn. The dentist not having any chloroform, and seeing that the tooth was quite loose, thought he might deceive her by holding a cupping-lamp to her nose; he then proceeded to open her mouth, when he found that she was dead. Bonvalot[32] relates the case of a young woman on whom an attempt at procuring criminal abortion was about to be made; the cannula of a ball-syringe was introduced into the os uteri, when the patient fell back before any of the fluid had been injected, and died in a few minutes. Many cases of sudden death during the actual administration of intra-uterine injections have been recorded. On more than one occasion death has suddenly occurred at the moment when a simple digital vaginal examination was being made. Brouardel[33] states that when he was a hospital "interne" one of the physicians digitally examined [an

Hosted by Google

in-patient; she died immediately before anything could be done to help her. Brouardel further states that he knows of two other cases in which women died suddenly in the consulting rooms of medical men whilst an ordinary vaginal examination with the finger was being made. Sudden death, apparently from cardiac inhibition, has been observed to occur when certain parts of the body are abruptly handled or compressed; these are the nasal passages, the larynx, the epigastrium, the urethra, the bladder, and the genital organs.

Young children are especially liable to sudden death in a number of ways which do not obtain with adults. Infants die very readily from suffocation. An infant has been innocently suffocated whilst being held by the mother to her breast; the child's mouth and nostrils were so closely covered by the yielding mamma as to cause fatal asphyxia without anything amiss being perceived until it was too late. Convulsions due to reflex irritation are a common cause of infantile death. An infant who "dies in a fit" thus produced dies from asphyxia occasioned either by tonic spasm of the respiratory muscles or of the glottis, or of both. The post-mortem indications of death from asphyxia thus caused cannot be distinguished from those found after death due to criminal or accidental suffocation (overlaying). The sub-pleural ecchymoses held to be indicative of death from suffocation are due to increased arterial blood pressure and are likely to be produced by convulsions. They may, however, be absent after death from convulsions. Spasm of the glottis, as in laryngismus stridulus or in whooping-cough, is another way in which infants are subjected to sudden asphyxial death. A like observation applies to œdema of the glottis. Hyperplasia of the thymus gland is occasionally observed post mortem and has been regarded as a cause of sudden death in infants. Whether death is due to compression of the trachea or bronchi by the enlarged thymus or to laryngeal spasm is a disputed point. As previously stated, young children are easily suffocated by food that has been taken into the mouth or regurgitated from the stomach finding its way into the air passages. Scarlet fever exceptionally ends fatally in eight or ten hours; convulsions, coma, rapid respiration, vomiting, and sometimes hyperpyrexia—110° to 115° F.—are among the symptoms. Finally, sudden death may occur to young children without any ascertainable cause. Hale White[31] mentions three cases in which death suddenly took place in children who were in hospital. In none of them was any coarse lesion found after death.

Manchester.

THE CARE AND MANAGEMENT OF EPILEPTICS IN COLONIES.

BY WILLIAM ALDREN TURNER, M.D. EDIN., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN, WEST LONDON HOSPITAL; PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR EPILEPSY AND PARALYSIS; AND VISITING PHYSICIAN TO THE COLONY FOR EPILEPTICS, CHALFONT, BUCKS.

APART from the actual necessity of lessening the severity or diminishing the frequency of epileptic fits by the administration of drugs, other important measures in the general treatment of epilepsy ought to receive attention, and more especially the care, education, and management of sane epileptics.

I.—CARE AND EDUCATION OF EPILEPTIC CHILDREN.

In the first place the care and education of epileptic children will be considered. For this purpose it is essential to separate those which are sane from the imbecile or idiotic. For the management of these provision has already been made throughout the country in the idiot asylums. The experience of the authorities at such institutions is that much benefit may accrue to epileptic children of this kind where, under careful supervision, regular habits as to food, exercise, and judicious instruction and employment, they improve sometimes to a remarkable extent. Such cases amongst the wealthier classes of society may receive similar attention and instruction in private institutions and homes. But it is more particularly the care and education of the sane epileptic children to which attention is at present being directed. It is difficult to obtain any reliable statistics upon the actual number of such cases, but a report of the Charity Organisation Society throws some light upon this subject. Of 372 children exempted from attendance at the elementary schools in London in 1891, 61 were stated to be epileptic.[1] Of 498,300 children under instruction in the London School Board in 1895, 259 were epileptic, and 226 known epileptics were not under instruction, or a total of 485 sane epileptic children known to the London School Board authorities in that year.[2] These figures probably understate the actual number of sane epileptic children in the metropolis. Reckoning the number of epileptics to the total population as 1·5 per 1000 (vide later) this would only give 0·97 epileptics per 1000 of the general school population, a figure which is too low. The reason of this is well known, for the causes are many and obvious why epileptic children are kept at home. Mainly as a result of this the education of the epileptic child is disregarded; as he grows older, owing to inability to obtain a livelihood, he becomes a burden to his relatives, added to which is the natural tendency towards blunting of the intellect which epilepsy produces, and he eventually drifts either into an asylum or the workhouse.

It is therefore an important point to inquire whether any provision can be made for the education and instruction of these cases. And, firstly, Is it right to educate epileptics along with other children? Most medical authorities are agreed that no harm results from mixing together at school the epileptic and non-epileptic. The fact exists, however, and it has an important bearing upon this question from the schoolmaster's point of view, that the presence of an epileptic has a disturbing influence upon his schoolfellows, as well as from the fact that by the nature of the disease the epileptic child requires special supervision. Although many epileptic children are bright and ready to acquire knowledge, the minds of a large number have, even at an early age, suffered from the blunting influence of their disease. Under such circumstances it is, on the whole, better that they should be educated apart from healthy children. It will be found, however, impossible to carry this out in all instances, partly because in some cases epilepsy exists unrecognised, and partly because the existence of this disease is wilfully hidden by the parents. It is, however, the education of obviously epileptic children that requires special attention. Many are of opinion that the epileptic child is placed at as great a disadvantage, educationally, as is the blind or the deaf-mute. So far, however, the legislature has made no recognition of this, nor has private generosity supplemented the deficiency. It would seem, however, as if the whole question of education in this and closely-related conditions is soon to receive attention, as a Departmental committee has recently been appointed to inquire into, and report upon, the education of feeble-minded children, not under the charge of guardians and not idiots or imbeciles, and of epileptic children. How this is likely to be carried out will no doubt form the subject of a report; but from the medical aspect the following suggestions may be made: (*a*) That where possible, and when there is no blunting of the intellect, or when the fits only occur at night or at long intervals, epileptics may be educated along with healthy children; (*b*) if there is no marked impairment of intellect, but the fits are frequent or severe, or special supervision is necessary, or from other like reasons, provision should be made for the education of such children separately from others; and (*c*) that if along with epilepsy there is feeble-mindedness, but without actual idiocy or imbecility, provision for the suitable education of such cases should be made, and preferably in colonies, such as will be presently described.[3]

II.—THE SANE ADULT EPILEPTIC.

Having drawn attention briefly to the education of epileptic children it is now intended to discuss more fully the management of the sane adult epileptic. Concerning the general prevalency of epilepsy in its relation to the total population there is difficulty, from many causes, in arriving at satisfactory statistical results. First, no census for this purpose has been taken in the United Kingdom, while those taken abroad are only partial; and, secondly, epilepsy

is so closely related in the early years of life to idiocy and imbecility, and in the later years to insanity, that it is almost impossible to satisfactorily separate them for statistical purposes. But a few facts may be given upon the estimated number of adult epileptics. In Germany the estimate is given as 1 per 1000,[4] in New York State as 2 per 1000 (Peterson),[5] and in the Canton Aargau in Switzerland at 2·5 per 1000 (Bircher) of total population.[6] In Italy, of 10,000 young men who presented themselves for military duties 11·5 were rejected owing to epilepsy (Morselli),[7] giving a proportion of just over 1 per 1000. It would not, therefore, be placing the number too high if it is stated that the probable proportion of adult epileptics to the total population is from 1 to 1·5 per mille in the European countries in which this subject has been looked into. A census has, however, been taken upon this subject in certain of the Australasian colonies. For instance, in the Victorian Year-book for 1894, p. 398, a table is given showing the relative proportion of epileptics to the total population. The number of epileptics was found to vary between 1 in every 2322 of population in South Australia, to 1 in every 3964 in Tasmania. The average number may be given as that found in the colony of Victoria, where the proportion of epileptics was stated to be 3 68 per 10,000, or 1 epileptic in every 2715 of population. This is found to be considerably below the estimate of the European countries and America; but indications have been already given of the difficulty in ascertaining the true facts about epilepsy, so that it is not improbable that the above numbers really under-estimate the total proportion of epileptics in the Australasian colonies.

Many epileptics are perfectly able to conduct business and to carry on work of an intellectual or mechanical nature with credit and without any harmful result. On the other hand, however, owing to the impairment of the mental faculties to which epilepsy gives rise, or from inability to obtain regular employment owing to defective training, or from the sudden onset of fits and the subsequent incapacity, many epileptics are unable to make a living. An epileptic artisan is absolutely debarred from many trades and occupations, such as building, engineering, &c., while in other cases the services of an epileptic workman are not desired by an employer of labour unless he be of an exceptionally indulgent and charitable nature. Hence in all classes of society the epileptic whose fits debar him from occupation becomes a burden to his relatives; while amongst the poorer classes he swells the ranks of the unemployed, and eventually ends in the workhouse. For instance, in a return made in 1893 by the Local Government Board for the National Society for the Employment of Epileptics[8] it was stated that in the Poor-law Institutions of London, specially examined, there were 34,889 inmates, of whom 604 were sane epileptics. Taking the ratio of epileptics to the general population as 1 per 1000, this would give about 3000 sane adult epileptics in the metropolitan area. As pointed out in the paper above mentioned, this makes one in every five of the total epileptic population of London an inmate of a workhouse, and it also shows that of the pauper inmates of the workhouse one in every sixty is an epileptic. The question, therefore, at the present time which is exercising the minds, not only of medical men, but of those who direct the organisation of Charity and of the Poor-law, is—Is there any way by which such individuals may be able to support themselves under care and supervision? and the answer is being given in this country and in America by the formation of colonies for epileptics. In Germany the formation of such colonies has already met with exceptional success. At Bielefeld, for example, 1100 epileptics are employed in various forms of field and garden work. They are maintained in houses containing from 14 to 15 up to as many as 50 individuals. But in addition to being an institution in which sane epileptics may find useful employment, it is also "a sanatorium, an institution for the education and instruction of epileptic children, and an asylum for imbecile epileptics."[9] The results of this method of treatment and general management may be obtained from a perusal of the reports of the colonies, not only at Bielefeld, but also at Zurich, Potsdam, and Stettin, where there are similar institutions. An average gives a percentage of about six "recoveries," and 30 or 40 per cent. may be stated to have so much improved as to be fit to leave the institution. A certain number of relapses, however, occur, for during one year (1889) of 212 admissions 30 were admitted for the second time. From the consideration of these reports it is evident that in the management of epileptics in colonies provision therefore has to be made, not only for the schooling of epileptic children and for the employment of epileptic adults, but also for those who, from the very nature of their disease, in the course of time become feeble-minded and demented.

In the Craig Colony for Epileptics, recently established in New York State, provision has been made for the education of epileptic children as well as for the employment of adult epileptics. This institution, which has been at work for only a short time, is fulfilling its function in a most satisfactory way. From the third annual report, recently issued, I gather that 145 adult epileptics are employed in the various forms of garden and farm work, and that there are twenty-three children in the school. The general effect of the colony life upon the epileptics is stated to bring about a marked improvement both physically and also as regards the number and severity of the fits. In England until two years ago there were only two small "homes" for epileptics—one at Maghull, founded in 1889 for the reception of both males and females, and Lady Meath's Home for epileptic girls.

In 1894 the National Society for the Employment of Epileptics opened the first House at the Epileptic Colony at Chalfont St. Peter, Buckinghamshire, and it is in connexion with the results obtained at this institution to which attention is especially drawn. In the management of the patients at this colony the same principles are carried out which have conduced to the success of similar institutions elsewhere. These may be briefly stated to be: (*a*) removal of the epileptic from the towns to the country; (*b*) the regular employment in the garden, fields, orchard, workshops, &c., of the colonists under the supervision of capable persons; (*c*) the maintenance of a well-ordered and regular mode of life, with the avoidance of excitement and abstinence from alcoholic liquors; and (*d*) abundance of good nourishment of a simple nature. Living under such conditions it has been found that the epileptic requires only a minimal amount of medicinal treatment, and it is the custom to give each colonist thirty grains of bromide of potassium at bedtime.

The present accommodation consists of two houses, each containing 18 male epileptics. A house to accommodate 24 female epileptics is ready for occupation, while the building of another house for men is progressing. It is also expected that in a short time two houses for children (male and female), with the necessary school accommodation, will be erected. Since the opening of the colony in August, 1894, 62 male epileptics have been under observation for periods of varying duration. Of these, one has left the colony after a residence of two years apparently cured, or at all events so far improved as to be able to resume work. One died from symptoms indicating sudden cardiac failure, one has been sent to an asylum, nine left the colony at their own wish, while eighteen were discharged for various reasons. Up to the present time payment is made on behalf of the colonist either by his relatives or by the boards of guardians interested in individual cases. Epileptics whose relatives are in a position to pay higher annual sums have not so far been admitted owing to the want of suitable accommodation, but as the necessary funds are now forthcoming it is proposed to erect a house for this class of patient. I may now consider briefly the effect of such general care and treatment upon the individual epileptics, and for this purpose look at it from the following points of view.

1. *Frequency of the fits.*—In the majority a marked diminution in the number of the attacks is observed after admission to the colony. This is probably due directly to the removal of the epileptic from bad hygienic surroundings in the town to a pure country air, with abundance of simple diet and a well-regulated *régime*. In a minority there is a temporary increase in the number of fits, which may be due to the fact that previously to admission larger doses of bromide have been taken, this being entirely withdrawn except for a small dose at bedtime. In both instances after a short time the average number of fits is struck, and this is found to vary largely in different cases. The greater number of fits occur during the day, and by far the commonest time is during the first hour after rising in the morning. The attendants have found that fits are rare on

going to bed, and that as a rule the patients are much better and brighter during the evening. A point of some interest is that more fits occur in the house than outside in the garden or fields, and this apart from greater difficulty in registering the number outside; while there seems to be a general impression that more fits occur during warm and close weather than during the cold.

2. *Severity of the fits.*—Here, again, there is a majority in which an amelioration in the severity of the attacks occurs, while in a minority no material alteration is noticed, and in some a decided tendency towards increase in severity. Upon this point, however, it is more difficult to obtain accurate observations. In some of the colonists severe fits gave place to attacks of *petit mal;* in others, attacks of an average nature became more severe.

3. *General mental state.*—In quite a minority there has been a progressive tendency towards dementia. In some it appeared to be the natural course of the disease. In others it was owing to the frequency and severity of the fits, or of both combined. In the greater number no such mental deterioration has been observed. On the whole, the mental state of the colonists, considering the duration of the disease, is good. Some of them are capable of work requiring individual alertness and tact, while most are able to do good work under supervision. But the greatest benefit which this system of treatment is capable of producing lies in the general moral effect which it has upon the individuals. These persons amongst the poorer classes are in many instances regarded as "family lepers," the outcasts of the community, between whom and their relatives there is little sympathy. In a colony each epileptic is readily brought to see that he is as useful a person as his more highly favoured brother if placed under proper conditions. Here interest is taken in his work, in his mode of life, and in his amusements, with the natural result that he takes greater interest in himself and obtains a feeling of higher self-respect.

4. *General physical state.*—It is under this heading that the greatest improvement has been noticed. Without exception the general health of each colonist has materially improved. They all put on weight, and this, notwithstanding the fact that they may be subject to frequent and even severe fits.

But it may be asked, What kind of work has been found most conducive to good health among the epileptics? It may be stated that all forms of work appertaining to the fields or the garden have been found beneficial, while good work is also done in the carpenter's shop by picked men. The farm of 135 acres is worked by the colonists with the addition of a few farm labourers and overseers (bailiff and gardener). In the summer months matches are arranged between the cricket club of the colony and the various local clubs of the district, but football is not allowed. Contrary to the experience of the authorities of the Craig Colony for Epileptics, it has been found that the granting of holidays to the colonists at intervals is of value. Certain important precautions are taken before leave is given, but on the whole such a change has been of material service to the individual. It is scarcely necessary to state that the colonists have been carefully selected by the medical committee from a large number of applicants. The points to which attention is especially directed are: Has the epileptic been unable to obtain employment? or has he been discharged from one or more situations by reason of the fits? Is he capable of work under direction? and a point of great importance lies in a statement upon the absolute freedom of individuals from attacks of violence, mania, or other symptoms indicating insanity.

By way of conclusion, a summary of the evidence collected by the Charity Organisation Society from the results of this method of treating epileptics in the colonies on the Continent may be quoted [10]: "Any attempt to provide for the treatment of epilepsy, if large numbers have to be considered, should combine school-teaching with medical treatment and supervision. For young persons and adults regular but not too laborious employment is necessary. For all alike, for the furtherance of self-control, and for healthy enjoyment a well-ordered home life is required, and these the colony system provides. Medically, if the serious nature of the disease be taken into account, the colony system produces the best results. For the worst cases, and to provide against the constant ailments of many of the colonists, hospital accommodation is necessary. This system will have to furnish accommodation suitable for patients of all classes, the highest who may wish to have the best fare and rooms, and the lowest. The growth of the colony system is remarkable. It meets a very widely-felt need. This need is not met in England, for it cannot be said that to provide a residence in a workhouse is sufficient, and that is all that is now done."

I have endeavoured to show in this article that the need has now been met in this country, and that this form of treatment is being successfully carried out at the epileptic Colony, Chalfont, Bucks.

Queen Anne-street, W.

[10] Report on the Epileptic and Crippled, 1893.

ON THE DIAGNOSIS OF CERTAIN SO-CALLED RHEUMATIC DISEASES FROM EACH OTHER AND FROM RHEUMATISM.

BY GEORGE PARKER, M.A., M.D. CANTAB.,
ASSISTANT PHYSICIAN, BRISTOL GENERAL HOSPITAL.

THE distinction between the group of affections due to rheumatism and those of different origin is a much discussed and difficult subject. The limits of this group have of late been extended in some directions and diminished in others. Reasons have been given for including in it the most unlike diseases, such as chorea and erythema nodosum, while others which were formerly included as typical instances have been removed and shown to be due to recognised microbial infections or pyæmia. This has been especially the case with most forms of scarlatinal rheumatism, of malignant endocarditis, and gonorrhœal arthritis. Many uterine and ophthalmic affections have been also excluded. On the one hand, arthritic symptoms have been largely discredited as a test; and, on the other hand, the type of the disease as seen in children does not seem more trustworthy, since, for example, endocarditis has been of late shown to arise from the poison of such different complaints as phthisis, gonorrhœa, and even typhoid fever. The fact is, as Dr. S. Mackenzie remarks, we have no single criterion of rheumatism. We are ignorant of its causes, whether it is at first a local disease, and if so where it arises in the body. We have only a bundle of symptoms, almost any one or any group of which may be present in other complaints. It is of little use to say that various causes produce identical symptoms when they affect the same organ, such as a joint. If there is no test for rheumatism we shall want to know whether the other causes producing similar symptoms have any distinguishing marks. It seems the most promising line of inquiry, then, to focus clearly our ideas of those affections which mimic rheumatism and produce like phenomena. Some of them may be capable of exact definition, and we may then by a process of exclusion arrive at a true conception of rheumatism itself. This, indeed, has been the most fruitful method in the past. Leaving on one side for the present chorea and some other children of doubtful paternity, there are a large number of skin, joint, and pyæmic affections to be considered, such as Osler's erythema exudativum, Quincke's œdema, Henoch's purpura, erythema nodosum, gonorrhœal, scarlatinal, diphtheritic, influenzal, and other forms of pyæmic arthritis, purpura hæmorrhagica, and hæmophilia. Every symptom of rheumatism is seen in one or other of these, but many of them have a distinct individuality and sequelæ which will enable us to withdraw certain cases of seeming rheumatism and refer them to their true parentage. As I happen to have met with several instances of these disorders of late I shall briefly refer to the chief types, with abstracts of my cases, and mention any points which are against a rheumatic origin. To return for a moment to the general question of diagnosis, it may be said that we should be largely guided by a history of previous rheumatic attacks; but this is undoubtedly very misleading and the source of much error, for such histories often refer to a previous attack of something else which bore a superficial resemblance to that disease. Especially is this true since some of the allied affections tend to recur again and again. Even endocarditis is no evidence of rheumatism, for, as we have said, it is produced by numerous causes. There is, indeed, no reason why one of

Hosted by Google

these affections should not occur in a person subject to rheumatism, so that even if the previous attack was really of that kind we must decide the case upon its merits. Of course, if rheumatism is really found far more frequently in connexion with one of these affections than in healthy persons we can argue a special relation, but its incidence on the general population is not accurately known.

The action of salicylates, too, is an uncertain guide. Their failure in an apparently typical case of acute rheumatism may lead us to consider carefully our diagnosis, but their reducing the pyrexia is no proof of rheumatism. A French writer has recently denied any specific action to them and considers that they merely exert a sedative or paralysing effect on all inflamed protoplasm. Whether this is so or not their action is not entirely confined to rheumatism. Thus we might be easily misled by them in cases of *influenzal arthritis* such as have been of late described by Dr. Sansom.[1] It is true that salicylates will often relieve the pyrexia and pains of influenza; but these cases where troublesome joint mischief accompanied and followed an attack showed from their course and sequelæ that they were certainly not rheumatic. In some of them the affection proved to be rheumatoid arthritis, which is a very different thing. Others developed into various forms of neuritis. In all there was little or no effusion within the joints, but the ends of the bones were tender and enlarged and the seat of most of the pain. In no instance has Dr. Sansom traced valvular heart disease to an attack of influenza, though dilatation, cardiac neuritis, and angina are not uncommon. Still, these cases were at first very like ordinary rheumatism. It is interesting to notice that some observers claim that salicylates will often relieve the crises of tabes, and of this I have seen some apparent instances, yet no one regards the arthritic symptoms of that disorder as rheumatic.

Henoch's purpura as originally observed by him in children was of a very definite type, presenting severe abdominal pain, intestinal and renal hæmorrhages, purpuric eruptions, often with vomiting, swelling of the joints, œdema of the hands and feet, and nephritis. Von Dusch and Hoche, and recently Osler, have collected some sixty cases, both in adults and children. If we refer to Osler's account[2] we find that he describes it as an erythema exudativum multiforme; but he notices that the skin affections may be absent altogether or appear only in one of the recurrent attacks which may present themselves year after year. The most constant symptom is a sort of gastric crisis, which may vary from a stomach-ache to an unbearable agony. With this there commonly comes on vomiting and diarrhœa, as well as pain and swelling rather around than in the joints. There is not unfrequently pyrexia, sometimes delirium, and nephritis of various degrees, from slight albuminuria to a fatal form with casts and anasarca. Hæmorrhages from the kidneys, bowels, and stomach are frequently seen, and recurrent attacks of bronchitis and hæmoptysis may occur, as well as eruptions of purpura, erythema, and urticaria; occasionally we meet with affections of the heart and spleen. Both here and in a very different disease—purpura hæmorrhagica—the melæna may arise from a slough and subsequent ulceration of the intestines, which causes, not only bleeding, but intractable diarrhœa and even perforation. The following is the history of a well-marked case under my own care for a time.

CASE 1.—A young seaman in perfect health was attacked on July 26th, 1896, by severe abdominal pain, for which he took castor oil. A little urticaria appeared and vanished as quickly. On the 28th the pain became intense, and he was found lying helpless and prostrate, with some tenderness to the right of the umbilicus, but the attack, though puzzling, was clearly not one of abdominal obstruction or appendicitis. The heart, the temperature, and the lungs were normal, nor was there any affection of the skin, kidneys, or joints. Some relief from the distress was obtained by the use of opiates, till on the 31st much pain and swelling of the wrists, especially of the right one, occurred. The temperature was still normal, but on Aug. 1st it rose to 100° F., and the pains became worse, with much aching in the thighs. Salicylates had little effect. An ulcer appeared on the edge of the tongue, as though a piece had been bitten out. On the 8th, and for a week onwards, the temperature varied from 100° to 102°, but meanwhile the arthritis disappeared and the appetite became good. After a sharp increase of the gastric pain, with vomiting and diarrhœa, on the 13th, these symptoms declined, but some dulness and diminished respiratory murmur were noted over the left scapula. On the 20th an extremely painful œdematous swelling spread over the right side of the scalp and forehead, and closed the right eye. There was no redness, and the pain was sufficiently severe to interfere with sleep, but the temperature meanwhile fell to normal and the appetite became voracious. In four or five days the swelling subsided, but on the 26th a purpuric rash appeared on the legs of a dull pale red, forming numerous close-set spots of the size of sixpence, extending a short distance up the thighs and accompanied with slight œdema. From this time gradual improvement set in, the patient gained flesh again, his anæmic condition gradually disappeared, and he returned to work on Sept. 11th sound and well in every respect.

On at least one occasion during the illness the vomit was blood-stained, and the apparent absence of any evidence of intestinal hæmorrhage may have been due to oversight in the nursing. It is noticeable that no history of poisonous food, pork, or shell-fish or of previous rheumatism was obtainable. I can see nothing in the general aspect of such cases when fully developed to entitle us to call them rheumatic. Dr. S. Mackenzie regards Osler's own group of eleven instances as a distinct form "where the hæmorrhages are accidental, not essential," but he appears to refer them all to the rheumatic class. Now it seems to me that there is a strong argument against this in the prevalence of nephritis, which occurred in fourteen out of the sixty-one cases reported; and in the rarity of endocarditis, which was present in only two out of sixty-one, and those not mild ones, for no less than thirteen were fatal. The occasional splenic enlargement is another point in the same direction. It appears rather that we have here a definite disease of an an acute toxæmic type, which I will call the Osler-Henoch, and which may be simple or hæmorrhagic. Many supposed cases of rheumatism are probably of this nature, which it is important to distinguish, if only from the difference in the sequelæ to be expected. It seems difficult, on the other hand, to look on this disease as erythema multiforme or purpura hæmorrhagica, since the eruptions may occur only once in four or five attacks, at any rate in adults. Dr. G. A. Sutherland,[3] in reporting recently three cases, looks on the joint symptoms as septic, though nothing has been discovered bacteriologically. Foreign opinion at the late Dermatological Congress was against any connexion with rheumatism.

Angio-neurotic œdema is a name given to another group of cases which are related in several ways to the Osler-Henoch disease. They are sometimes spoken of as Quincke's œdema, and the attacks are often ushered in by severe gastro-intestinal pain and disturbance. In one variety large patches of œdema of irregular shape appear on various parts of the body.

CASE 2.—A patient of mine, a widow aged fifty-two years, has suffered from it for several years. The wheals or patches recur frequently on the left cheek, the lower lip, and on the eyelids, where they seem almost fluid and transparent. There is no pain, redness, or itching, but a little pricking when the patches begin to swell up, which takes place every few days. She enjoys otherwise good health, but gives a history of "rheumatic fever," which may or may not be correct; there is no cardiac murmur. Two or more fingers in each hand are affected by lesions which appear to be those of rheumatoid arthritis and grate on moving. On the right olecranon and on the left wrist are subcutaneous nodules. The latter, again, it should be noted, are not found in rheumatism alone. Jamieson speaks of the frequently observed connexion of this œdema with rheumatoid arthritis, but beyond this nothing is known of its pathology. No relation whatever to true rheumatism has been made out, though fugitive œdemas, apart from the arthritis, do sometimes appear in the latter.

In *rheumatoid arthritis* we see another well-defined disease distinct from rheumatism, yet presenting many of its ordinary symptoms. Bannatyne and his fellow workers have apparently shown that in this complaint we have a toxæmic infection by a bacillus with irregular pyrexia, sweating, and tachycardia, and not infrequently pigmentation of the skin and purpura. Hæmorrhage from the mucous membranes is very rare, with the exception perhaps of hæmatemesis. The joint affections and muscular atrophy are the most commonly

noticed symptoms, and it is remarkable that the great majority of the sufferers are women. This predilection for the female sex is shown, curiously enough, in the cases of erythema multiforme and purpura which Dr. Stephen Mackenzie collected as showing the so-called rheumatic history, the proportion being four or five to one. Another point of similarity with these diseases and Quincke's œdema is the occurrence of gastric crises which may be severe and periodical. Well-marked instances have been recorded by Dr. H. Waldo, and a typical patient of my own, thirty-two years of age, unmarried, complains of them strongly, as well as of the ordinary joint troubles. The history of the patients, the joints affected, the deformities, the sequelæ, and the results of treatment are other well-known points wherein this disease differs from rheumatism, though it bears a superficial resemblance.

I must only refer briefly to certain forms of *septic arthritis*, many of which are clearly non-rheumatic. Such are those seen in gonorrhœa, scarlet fever, diphtheria, especially that following the use of antitoxin, variola, and erysipelas. We may at once dismiss the purulent effusions. Gonorrhœal arthritis is intractable, tends to develop adhesions, and affects special joints, such as the temporo-maxillary, and is sometimes accompanied by purpura and endocarditis where the gonococcus has been isolated. Serous scarlatinal arthritis has usually been accepted as rheumatic. Here again fuller knowledge has narrowed the field. Dr. R. W. Marsden[4] points out that the affection is either (*a*) a simple synovitis which occurs about the sixth day and is six times more common than all the rest put together, (*b*) septic, (*c*) tuberculous, or (*d*) true rheumatism. The last only occurs during a late stage of convalescence, and is always subacute. The early type with which it is usually confounded never recurs, is not accompanied by sweating, does not fly from joint to joint, rarely if ever affects the heart or shows any other rheumatic sequelæ, and is specially apt to develop in the tendons on the back of the hand rather than in the wrist-joint. The true rheumatic type is rarer even than the purulent forms, and appears in a quite insignificant proportion of cases.

Infective endocarditis may present joint affections, sweats, and purpuric rashes, and was formerly regarded as rheumatic in origin. In fact, the transition in the symptoms from septic cases to ordinary rheumatic endocarditis is marked by insensible gradations. Still, it is recognised that most malignant cases are produced by strepto-, diplo-, or staphylococci, though the presence of the lesions of former rheumatic endocarditis favours the outbreak of the disease. Very rarely, says Dreschfeld, it may complicate or follow acute rheumatism. It is usually, if not always, a septicæmia. The symptoms at first may resemble in some degree those of Henoch's purpura, as in a case of my own, where a somewhat purpuric patch went on to gangrene of the finger where it occurred; but the peculiar sweats and pyrexia, the heart signs, and the emaciation are soon distinctive.

Hæmophilia is, indeed, a permanent and hereditary condition, due possibly, as Wright suggests, to a deficient formation of polynuclear corpuscles; but we often meet with attacks in those suffering from it which resemble rheumatism. There is suddenly felt a discomfort and sensation of tension in various parts of the body, the joints swell and become painful, so that the epithet "rheumatic" has been applied to them even by Bristowe. Purpuric spots and hæmorrhages follow, though no wound has been received, and of course hæmatemesis and melæna may occur. Yet this apparent arthritis is probably due merely to hæmorrhage in or around the joints; the throbbing will be felt around any wound far away from a joint before renewed bleeding, as I saw lately in a patient under the care of Mr. Fendick, and the purpuric rash is also produced by any slight blow. Other symptoms of rheumatism are wanting and the disease is limited to the male sex.

The still rarer affection called *pulmonary osteo-arthropathy* seems to have no connexion whatever with rheumatism, though the joint affections may be easily mistaken for it.

To turn to *erythema multiforme*. We have seen little reason for looking on the Osler-Henoch type as rheumatic, but this has been asserted with respect to the other forms. Kaposi notices the joint pains, occasional pyrexia, endocarditis, and meningitis sometimes seen in them, as in other septic affections; while Coulard and Garrod show that a rheumatic history is very common indeed. Erythema nodosum especially is claimed as certainly rheumatic, chiefly on the ground of the great number of patients who have such a history, and partly because the two affections occur together not infrequently. Thus Mackenzie found this conjunction in seventeen cases out of 108 collected from various hospital records, besides twelve others in which the erythema followed rheumatism. The symptoms most relied upon were arthritis, sweats, and sore-throat, while endocarditis developed in some patients at the time of the attack. Even the value of this strong evidence depends on the strict analysis of the cases. As I have said before, joint pains and endocarditis are not uncommon in many septic diseases, and may have been taken for true rheumatism by the compilers of these records if they chanced to be less careful and accurate observers than Mackenzie himself. It is a curious fact that erythema nodosum, which the English and Vienna schools distinguish so carefully from erythema of other kinds, is often accompanied by them and by purpura, the various rashes being visible on various parts of the body at once. The causation of the various erythemas is not easy to reconcile with theories of rheumatism. They often follow the ingestion of noxious food and occur in epidemics in spring and autumn. Both the other varieties and erythema nodosum are most common in women (nodosum being particularly rare in males) during early life or when suffering from some uterine disturbance. The meningitis, gastric troubles, and renal hæmorrhages occasionally seen in them are unknown in pure rheumatism. In any case, as the *Dermatological Journal* remarks, there are on Dr. Mackenzie's own figures 50 per cent. which show no rheumatic symptoms or histories whatever. If erythema nodosum has any connexion of the kind it is probably only that one disease favours the invasion of the other, and not that erythema nodosum is rheumatism attacking the skin.

In *purpura hæmorrhagica* there is another toxæmic infection of definite character, though the skin and other symptoms are occasionally almost indistinguishable from purpuras occurring in rheumatism. The following was a severe case which I attended recently.

CASE 3.—A young man developed a slight purpuric rash at Easter last. He remained at home for a few days and then returned to work, though the eruption continued to appear for some weeks. He felt perfectly well, but the rash at last began to increase, and besides the petechiæ dark-coloured blebs were now seen, which were especially noticeable on and under the tongue and upon the soft palate; a little hæmorrhage from the gums followed. He then presented himself at the Bristol General Hospital as an out-patient, and was with difficulty induced to come into the house, where the next day he died from a hæmorrhage in the brain.

In such cases we often find every evidence of septic intoxication, fever, sweating, joint pains, and a comatose state. Moreover, there is some evidence as to the agent causing the condition. Tizzoni, Babes, Kolb, and Letzerich have all found bacilli present in the tissues and blood of patients which reproduced it in a modified form in animals, and Letzerich managed to infect himself from his pipe during his researches on the subject, and suffered a pretty severe attack. Watson Cheyne also found colonies of bacteria inside the vessels in two cases, though he failed in others. Quite recently Hayem and Rendu showed that the clot formed from the blood in this disease does not contract and squeeze out serum as it does with normal blood, or, indeed, as the clot does also in the secondary non-hæmorrhagic purpuras, which I shall speak of below. Besides the gastric and other hæmorrhages and occasional persistent diarrhœa from ulceration of the intestines, large areas of the skin may be rendered gangrenous by the hæmorrhages. Now, definite as the disease is, several cases where these severe bleedings occurred have of late been claimed as rheumatic Thus, we find one reported by Surgeon-Captain Fayrer, where the tongue and part of the penis were destroyed by gangrene, though the patient, a healthy soldier, regained his health; but it is surely more rational to regard the symptoms as ordinary effects of the purpuric toxin instead of exceptional ones of the unknown rheumatic poison. Even if the attack concurs with one of acute rheumatism, as in a rare instance related by Dr. S. Mackenzie, we know that such coincidences are met with in other diseases; that pure phthisis is exceptional; that rheumatism itself chooses injured joints, and bacteria when injected into the tissues show the same predilection; while the typhoid bacillus so intensifies the bacillus coli that the latter produces a large part of the intestinal

[4] Medical Chronicle, Aug. 5th, 1896.

Hosted by Google

lesions. Similarly, these two diseases do at times coexist, and possibly one favours the growth of the other. In the great majority of severe attacks of rheumatism, however, there is no indication of anything of the kind, and the purpuric complication is at best a rare one. The simple forms of purpura which do not affect the mucous membranes or produce hæmorrhages are produced under various conditions. We find them caused by drugs such as iodide of potassium, and again in cancer, heart disease, and leukæmia. I am not concerned to deny the occurrence of this symptom in rheumatism any more than its appearance with arthritis after the injection of antitoxin, or during a streptococcal pyæmia. As Dr. S. Mackenzie describes it, during ordinary rheumatism, or before an attack or after, the patient may complain of a dull pain or feeling of tension in the legs. Towards evening or during the next day small red spots appear symmetrically on both legs and soon take a purple tinge, while the discomfort passes away. Successive crops follow and may even spread to the arms, but any hæmorrhage is extremely rare. Out of forty-two of his cases rheumatism was present, or had occurred in thirty-five, and pyrexia was found in a third of them. I do not know of any evidence to show whether this form is really the effect of rheumatism or of a secondary infection, but some authorities who accept a rheumatic purpura make peliosis a distinct disease, and include under it a large proportion of such cases. They define it as marked by arthritis and a rash appearing around the joints, papular at first, and then hæmorrhagic, sometimes followed by intestinal ulceration and diarrhœa. It is, they say, unaffected by salicylates and rarely causes endocarditis. Dr. Mackenzie found albuminuria and abdominal pain in about a tenth of his cases, which is rare in rheumatism, though not unknown, especially where endocarditis has occurred. Thus it is probable that many of these instances are really purpura hæmorrhagica, or the Osler-Henoch disease, though symptomatic purpura may be found in rheumatism as a result of blood changes.

To sum up, we find that a large number of diseases formerly included under rheumatism have been gradually differentiated from it. First this was done with respect to gout, then many septic joint disorders were separated from it, and now the diseases in the group under consideration are shown to have definite characters, histories of their own, and to be followed by lesions, such as nephritis and neuritis, unknown in rheumatism. This enables us to place under them also many ill-defined cases usually regarded as rheumatic from the joint and heart symptoms present, for close observation shows in them symptoms quite different from those of rheumatism, though common in the diseases referred to. Lastly, these affections do sometimes coexist with rheumatism and produce their own symptoms, and, indeed, they possibly favour the evolution of rheumatic outbreaks, and are themselves aided by its presence.

Clifton.

CLINICAL TYPES OF PNEUMONIA.[1]

BY W. J. TYSON, M.D. DURH., M.R.C.P. LOND., F.R.C.S. ENG.

SENIOR MEDICAL OFFICER, VICTORIA HOSPITAL, FOLKESTONE.

I HARDLY know of anything more interesting in one's spare hours than to read a book on general medicine or surgery written fifty years or so ago. What an immense change has come about in almost every department of our profession whether the etiology or treatment of disease be considered! I well remember some twenty years ago, whilst dressing for the late Mr. Cooper-Forster, seeing a woman who was dying from acute septicæmia after an amputation of the breast had been performed, Mr. Cooper-Forster then remarking that it was impossible to account for these deaths, and that every now and then such a result would follow from an operation as the above. Even in my own recollection one most important disease has almost disappeared—viz., ague—and another—i.e., lardaceous disease is becoming very rare; the former forty years ago was rife in my own neighbourhood, and the latter was common when I was a student.

[1] A paper read at Rochester on March 19th, 1897, before the members of the North, West, and East Kent Districts of the South-Eastern Branch of the British Medical Association.

Before coming to the subject of my paper—the various types of pneumonia that are met with clinically—I will consider the past history of pneumonia. There can be little doubt that what is called to-day croupous, or lobar, pneumonia was the only form of the disease known to our forefathers. Watson, writing in 1848, in the third edition of his "Practice of Medicine" practically only describes lobar pneumonia; he gives a few lines to catarrhal or lobular pneumonia, but omits all reference to its pathology, physical signs, and treatment. Fibroid pneumonia he does not mention. Watson at the above date pictures most graphically all the classical signs and symptoms we now generally associate with an acute attack of sthenic pneumonia occurring for the most part in a young person from the so-called cause of chill, such as fine crepitation followed by bronchial breathing, bronchophony, dulness on percussion, the characteristic sputum, the relative increase of the respirations as compared with the pulse-rate, &c.; but, strange to say, the "crisis" is not referred to at all, probably, I suppose, because the thermometer was not in use at this date—still one would have thought that the application of the hand and the often collapsed state of the patient at this critical time would have demanded some special notice to this point. It was in this form of the disease that one, or sometimes all, of three well-known so-called specifics were used—viz., bleeding, tartar emetic, and calomel. The confidence in the foregoing was unbounded, and it would have been almost impossible for anyone not to have employed them, such was the faith in their efficacy. Graves, writing in his "Clinical Medicine" some few years before the period I have just referred to, speaks only of croupous pneumonia. He mentions as a rather common sequela or complication of the disease abscess of the lung; but on carefully reading over the notes of the cases there is some doubt in my mind whether these were not for the most part local empyemata or tuberculous cavities. However, at this date no exploratory needling or incision was made. Graves also recommends the old treatment of bleeding, tartar emetic, and calomel, but he advocated, as a rule, only two bleedings of twelve ounces at each time. The treatment by digitalis and strychnia is not mentioned at this date. My own reading and experience lead me to think that ordinary sthenic croupous pneumonia is not met with so commonly to-day as it was some years ago. I rarely see in hospital or private practice the disease accompanied with all the well known—I was going to say the examination or text-book—signs and symptoms. I believe that the type has somewhat changed. The various clinical varieties that are present with us now are in some instances due to different causes and require different treatment.

The phrase "congestion of the lungs," too, is constantly employed by the public and not infrequently by the members of the profession. It is quite difficult to understand in what sense it is used by the latter; when used by the former I pay no attention to it. Many years ago Dr. S. Wilks was constantly objecting to the prevalent use of the word "congestion," and he taught, I believe, that the term should only be used when the first stage of pneumonia was indicated. There can be no doubt that the first stage of a croupous pneumonia is that of congestion; but the question before us is, Is there such a thing as a congestion of the lung, pure and simple, apart from its association with pneumonia, and one that is not passive in origin, as seen in heart disease? I think that such a condition—which may be called "simple congestion" at present for want of a better term—does exist. It is almost impossible to demonstrate it as it is not a cause of death. The following case came under my notice a few weeks ago. A man, middle-aged, was admitted into the Victoria Hospital, Folkestone. At the base of the left side there was dulness on percussion, with bronchial breathing and bronchophony. On the right side at the base there was some loss of tone on percussion, with fine crepitation, but no bronchial breathing and no bronchophony. At the post-mortem examination the base of the left lung was found to be in a state of red hepatisation, with the characteristic appearance and qualities, and the base of the right lung in the condition known as congestion or engorgement. Now most of us have met with cases which gave only the signs that go with a congestion, and the subsequent history of the case has led us to make no further diagnosis. I see no reason, judging from analogous states in other organs and parts of the body, to say that this congestive state of the lung must necessarily go with pneumonia. On the other hand, I think the public and many of the profession use the word far too frequently and far too loosely.

When the term croupous or sthenic pneumonia is used in this paper it is that form which I have already mentioned as having been graphically described by Watson, with its well-known classical symptoms and signs, followed by crisis, generally supposed to be caused by exposure to cold. It occurs for the most part in youth and the middle aged, and the prognosis is good. The following forms, I think, we are justified in speaking of as clinically different.

Pneumonia of influenza.—It is very difficult to form an estimate of the proportion of cases of influenza that complicate pneumonia; but this complication is more frequent in some epidemics than in others, and I have sometimes thought some of our brethren seem always to have a very much larger number of pneumonia cases than others. This is probably due to the cause of a different method of classifying some of the chest troubles. The following seem to be the main and prominent characteristics of this form of pneumonia. The consolidation is not as a rule confined to one lobe; it begins in small patches, being more of the type of lobular pneumonia, although by the confluence of the various patches a large area of the lung becomes affected. It is rapid in its extension, and often both lungs are involved. The signs of bronchial breathing and bronchophony are not well marked, but crepitant râles are prominent. The cough is troublesome; the sputum is often profuse, and does not possess the ordinary sticky and rusty-coloured quality. I have seen two fatal cases of influenzal pneumonia, and the rapidity of the extension of the disease was remarkable in each case. No case of ordinary sthenic pneumonia has come under my care in connexion with influenza, although it is said to occur.

Septic pneumonia.—This form seems to be met with more frequently in young adult life or in middle age, and is seen rarely after sixty. The cause is not always easy to fathom, for the origin of the infection may be in some pent-up pus undiscoverable during life. One of the most typical cases ever seen by me followed an attack of facial erysipelas. The pneumonia is patchy in distribution, and whilst one patch is clearing up, another is appearing somewhere else, either in the same lung or in the other. The physical signs are not well-marked, and, of course, change as the disease shifts from one spot to another; the percussion note is impaired, but not very noticeably; bronchial breathing and broncophony are often present. The temperature follows a septic course, and the general appearance of the patient is one of blood-poisoning. There is no sputum, the disease is chronic in its course, and fatal in prognosis. The bacillus streptococcus is present in some cases.

Epidemic pneumonia. — The epidemics of pneumonia described as happening in the sixteenth, seventeenth, and eighteenth centuries are difficult to follow out and to understand; they are described pretty fully by Hirsch, of Berlin, in his "Handbook of Geographical and Historical Pathology," published by the New Sydenham Society in 1886. The epidemics existed in almost every part of the world. In reading the acounts of the above one feels that there is want of detail and accuracy about them which takes away very much of the value of the reports given. We must not forget, however, that auscultation was not practised or understood until the beginning of the present century, and the value of the thermometer is of recent date. It is during the last ten years that reliable knowledge has been obtained in reference to this form of pneumonia. An epidemic broke out in Middlesbrough in 1888 and was thoroughly investigated by the late Dr. Edw. Ballard. Two years later a similar epidemic, although on a smaller scale, occurred in the village of Scotter, in Lincolnshire, and was examined and reported on by Dr. H. F. Parsons. The disease appears to be a constitutional infection—a pneumonic fever. The incubation is short. There is a rapid rise of temperature and the constitutional disturbance is out of all proportion to the evidence of the local pulmonary disease. The cough is trivial. Delirium is early present. The fatal cases occur often on the third or fourth day. It is common for the physical signs of pleuro-pneumonia to be observed in one or both lungs on the second day. Convalescence usually begins by crisis on the seventh day. Relapse is common; mortality is high.

The infection is given off or tends to be given off, in the breath and sputa, and it is acquired by inhalation and perhaps by swallowing. The ease of transmission from person to person is much influenced by lowered vitality on the part of the recipient, and by close and prolonged contact with the patient. The treatment is thus important. The ordinary preventive measures of isolation and disinfection must be carried out.

Typhoid or asthenic pneumonia.—This comes on in a diseased condition, and therefore the clinical type is changed. The so-called typhoid symptoms are generally present, such as low delirium, tremors, paralysis of the sphincters, a brown, dry tongue, sordes on the teeth, the pulse feeble and rapid, &c. The pneumonia begins gradually, and is never sharply defined. The symptoms of rigor, pain, and rusty sputum are absent, and there appears to be no crisis. For the above reasons this complication, as it may be called, is often overlooked, yet it may be the immediate cause of death. In most cases the pneumonia is due to the pneumococcus of Fränkel; in some few, however, the typhoid bacillus has been found.

Pneumonia of the aged.—The pneumonia of old people certainly seems to me to carry with it a certain combination of signs and symptoms differing from the described preceding types. The disease comes on very insidiously and is accompanied with a general weakness of the body, which may overshadow the lung mischief. There is no rigor, no pain, and little cough. The temperature is probably little raised throughout, often not rising above 100° or 101° F.; the pulse at first is not much quickened, but the rapid increase of respiration is marked, and the patient complains of want of air. The patient lies on the affected side. There is little if any expectoration. The physical signs of dulness, bronchial breathing, and crepitation are all present, but the dulness is not great, and the crepitations are coarse in quality. The prognosis is bad. It is important owing to the latency of this form of pneumonia to examine the lungs in all acute illnesses of the aged. The above must not be confused with that which is known and described as "hypostatic pneumonia"; this latter state comes on at the end of an illness, being found in both lungs, and at the most dependent positions. Strictly speaking, it is a passive condition.

Alcoholic pneumonia.—This form is the last I will mention. Alcoholic pneumonia can be better recognised when seen and examined than when described. The delirium which is constantly present calls out for much attention, whilst the chest mischief may be proceeding unnoticed. The man is much worse than his physical signs would lead one to expect, and it is the general downhill condition of the patient that strikes one rather than any local disease. The sputum is profuse and dirty in colour, whilst the temperature is only moderate in height, and if the patient lives long enough the crisis is a feeble one. The prognosis is bad. I may say that as a rule low temperatures and profuse expectoration I have always looked upon as bad omens in forming a prognosis.

Probably most of the types of pneumonia I have been describing are pathologically almost identical, differing more in degree than in kind from one another. However, we know that when meeting with these varieties the prognosis and treatment are unlike in nearly all of them. Let me take as examples one or two diseases in each of which there are forms which pathologically seem alike and yet prognostically and therapeutically are dissimilar. Diabetes in people under forty years of age is a serious disease. The prognosis is bad, yet a case may be much improved by treatment. Diabetes coming on in persons aged over sixty years seems to be almost a harmless disease, and very often, except for the attendance of the medical man, would not be taken heed of by the patient. Clinically these two forms must be classed differently, but as regards the presence and even amount of sugar they are alike. Again acute Bright's disease following scarlet fever, as far as the urine and general symptoms are concerned, is identical with that form following exposure to cold. Yet we know clinically that the prognosis in the former is much better than in that of the latter. So I might give you other instances, but the above will suffice.

In a paper read a few months ago before the members of the West London Medico-Chirurgical Society [2] I advocated that there should be a more precise clinical classification of disease, and that it is unscientific as well as unpractical to speak of pneumonia, peritonitis, meningitis, neuritis, &c., unless some qualifying adjective is used to indicate the nature of the disease. I have attempted here to classify pneumonia clinically, although probably not entirely satisfactorily.

Bacteriologists wish and believe that various forms of disease should be classified according to the micro-organism to which the particular form is due. This method at first

[2] A Plea for a more Precise Classification of Disease, THE LANCET, Jan. 16th, 1897, p. 180.

Hosted by Google

sight would seem a simple and satisfactory one, but practically bacteriology is not in such a sufficiently advanced stage for us to adopt this mode. Before many years are passed—the clinical physician and the bacteriologist working more closely together, each correcting and aiding each other—we shall arrive at much more satisfactory classification of disease than at present exists. In the meantime I think that there is room for the clinical physician to be more accurate in his own line than sometimes he has been in the past, hence the reason why I have written my paper on the clinical types of pneumonia.

Folkestone.

A CASE OF STRICTURE OF THE RECTUM.

BY JAMES DUNLOP, M.D.Q.U.I., L.R.C.S. EDIN., &c.,
FLEET-SURGEON R.N. RETIRED.

A WIDOW, aged sixty-nine years, of strong constitution and the mother of thirteen children, had an attack of constipation on April 19th last year while in the south of France, accompanied by abdominal pain, increase of temperature, and vomiting, from which she recovered. Enemata, some with turpentine, were assiduously used until the bowels acted; poultices were applied, and purgatives were given. On May 15th the patient arrived in London, where she again used purgatives to combat constipation, and on one occasion had to keep her bed for several hours, owing to nausea, until the bowels acted. On the 29th, when in Ireland, she had another attack of constipation without rise of temperature or local pain, which yielded to the previous treatment. A fourth attack occurred on June 12th, and five grains of calomel were given. This was followed by nausea and vomiting; retching continued for some time; enemata were then tried, but nothing came from the bowels except a small quantity of a tar-like substance. On the 15th a specialist was called in by the medical attendant. He stated that he made a digital examination of the rectum and carefully examined the abdomen, and that he could detect no stricture or organic disease, and was unable to say what caused the constipation. He further stated that the bowels were so little distended that if there were any organic tumour, impaction of fæces, or stricture, he believed that he would have felt it. He considered that from some unknown cause there was paralysis of a portion of the intestinal canal, similar to that which occurs after a surgical operation, and that by rectal alimentation and the administration of purgatives, combined with medicines to give tone to the intestines, all would come right. Cascara, nux vomica, and belladonna were prescribed. From the 17th till the 30th the bowels acted irregularly, diarrhœa followed the medicine and constipation ensued when it was omitted. The dejecta were fluid and much broken up, on three occasions they were described as small and of a coffee-ground colour. The anticipated relief was not experienced. On two occasions the consultant was told of her condition and he advised her medical attendant to persevere with the medicine. On the 30th, the bowels acted once; the stool was scanty, and semi-fluid; flatulence and nausea were troublesome. From this date till July 6th, there was no action of the bowels. There was no vomiting unless medicine was taken; enemata of glycerine, aloes, soda, turpentine, &c., were used without relief; the patient was in bed and the temperature was normal. The consultant again saw her and found that the bowels were too distended to permit him to examine the abdomen as he had done on his first visit. He stated that a portion of the intestine was filled with fæcal matter, but that it was soft and doughy on pressure. Tincture of belladonna was prescribed; nutrient enemata of peptonised milk and yelk of egg every four hours; no solid food to be taken; tepid water to be used every twenty-four hours to wash out the bowel; expectant treatment to be relied on. On the 13th the medical man who had attended the patient in France, met the specialist and the regular medical attendant in consultation. Absolute constipation had been present from June 30th; the abdominal distension had increased; coils of distended intestine were easily felt and observed raising the abdominal walls; there were marked borborygmi and flatulence, but no vomiting or pain on pressure, the temperature being normal. Pills, each of a quarter of a grain of calomel with two grains of colocynth and hyoscyamus were ordered; one to be taken every two hours until the bowels were moved. By July 17th twenty-nine of the pills had been taken; the bowels had not acted, and the pills had to be omitted because of the irritation of the stomach. The retching was painful to witness; the lips were parched, and the patient almost incessantly sipped cold water; the abdomen became more distended, but there was no pain on pressure. On the 20th there was no improvement; after a tepid water enema, some matter, like shreds of membrane, was expelled. On the 22nd the patient was more cheerful. Two of her sons, surgeons, arrived from London, one of whom expressed his opinion that nothing except an operation could then save life. Consequently, on the 24th, a professor of surgery and the specialist were called in consultation with the medical attendant to consider the advisability of operating. The patient's bowels had not acted for twenty-four days. On examining the patient they found the temperature to be 98° F.; the pulse 92, weak and regular; there was no pain; the abdomen was much distended and pear-shaped; there was tympanites, which did not interfere with chest organs; the liver was displaced upwards; and there was a duller note along the descending colon, which was greatly distended. They considered it inadvisable to operate, but the professor of surgery was of opinion that "Hutchinson's taxis" might be tried if the conditions were not soon spontaneously relieved. An enema of cajuput and assafœtida was given and it was advised to elevate the foot of the bed for fifteen or twenty minutes daily. On the 25th the patient was much the same. A telegram was sent in the evening to a London surgeon. A very brief recapitulation of the case was given and the question asked, "Is colotomy advisable"? The reply was, "Patient is sure to have stricture somewhere in colon or low down in small intestine. Should advise abdominal exploration in middle line of abdomen to find situation of stricture, and then open gut above stricture, bringing it to surface at the most convenient part of abdomen." On the 26th the patient was depressed and worse. The same consultants as on the 24th were called in and requested to come prepared for immediate operation. The telegram was submitted to them to strengthen opinion should they consider the patient had sufficient strength to bear an operation. The opinion held by them was that abdominal section in the patient's present state was unjustifiable. On the 29th another consultant was called in. He examined the abdomen externally before the medical attendant, and expressed his opinion not to operate, but to wait for more urgent symptoms. The bowels had not acted for thirty days and all the signs and symptoms were more grave. Hypodermic discs of one-sixth of a grain of sulphate of morphine with $\frac{1}{150}$th of a grain of atropine were prescribed, one every eight hours placed under the tongue, under the impression that the constipation was caused by a spasmodic stricture of the intestine, which would yield once the system was completely under the influence of opium. The last consultant saw the patient on Aug. 1st, 5th, and 10th. The treatment was continued as it gave the only relief the patient had from urgent symptoms. On the 12th, the bowels not having acted since June 30th, at 10 P.M. an œsophageal tube was attached to a syringe and very carefully passed for twenty-four inches into the bowel. When about seven or eight inches in it seemed to move along a curved surface with difficulty, and then suddenly to glide forward. A tepid water enema was thrown up and retained. On withdrawing the tube about half a pint of semi-fluid fæces, greatly broken up, was expelled; the tube was covered for about sixteen inches from its distal end with tenacious fæcal matter. The next two days, after an enema had been given in the same manner, a similar discharge was noted. On the 15th, as the patient was sinking, the last consultant was again brought. He prescribed various cardiac stimulants, some to be administered hypodermically. On the 16th there was much restlessness and perpetual movements of the hands in jerks. Consciousness was retained until a few hours before death, which occurred at 4 15 A.M.

Remarks.—The bowels had not acted for forty-two days. Life during that period had been sustained chiefly by rectal alimentation. A necropsy was performed thirty-five hours after death. The abdominal cavity and its organs were healthy; there was no effusion or escape of fluid into it. The small intestine was normal throughout; the large intestine was enormously distended, but healthy as far as the rectum, and was gorged

Hosted by Google

with semi-fluid fæcal matter. Nothing was observed to account for the obstruction, and the examination was about to be given up, when one of the deceased's sons urged the necessity of examining the rectum. An annular stricture of the latter was found in its first portion, just below the sacral promontory, with puckering of the gut above and below it. The stenosis was about an inch in length, and its calibre was not greater than to admit the tip of a man's little finger; it tore easily, as sloughing had commenced; there was ulceration. A piece of the gut was retained for microscopical examination. No sections were then made of the specimen, as it was considered very rare and worthy of being exhibited at the first available meeting of the Ulster Medical Society to be held in December. In April, 1897, I forwarded the specimen to the Clinical Research Association in London and received the following report with two prepared slides:—"The enclosed sections have been made through the ulcerated and strictured portion of the rectum. In consequence of decomposition the tissues have failed to stain, and much of the growth has disappeared. But this much can be made out. There is a deep ulcer in the wall of the rectum which has excavated the muscular coat and almost perforated it in the centre of the ulcer. Among the muscular fibres there are oval spaces which contain a few distorted cells and some granular matter. At the edge of the ulcer the Lieberkühn's follicles of the normal mucous membrane are seen. From the characters of the ulcer, and the situation of the spaces or alveoli in the muscular coat, there can be no doubt that the stricture is due to a deeply ulcerated malignant growth which has invaded the entire thickness of the wall of the rectum. Such growths are invariably columnar—called carcinomata when primary in the colon—and there is no reason for doubting that such is the present case. It is also well known that carcinoma may produce an exceedingly tight annular stricture of the colon, with very little evidence of new growth owing to the ulceration which accompanies it."

Ballylesson, Belfast.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PERSISTENT SYMMETRICAL SUBCUTANEOUS FIBROUS NODULES IN AN ADULT, ASSOCIATED WITH MITRAL ENDOCARDITIS.

BY MAURICE EDEN PAUL, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

AN able-bodied seaman in the British Navy, aged twenty-five years, came under my care on March 29th, 1896. No history of rheumatism, either family or personal, could be obtained. The patient first noticed the nodules about a year previously; they had been steadily increasing in size and number. He applied for advice because the nodules over the hips pained him when he lay down; otherwise they caused no pain or inconvenience, and he did not regard himself as ill. He was, indeed, the "strong man" of the ship. Over the upper part of each femur, on the outer aspect of the limb, about three inches below the great trochanter, there was a group of nodules, ten or twelve in number, each nodule being about three-eighths of an inch in diameter and a quarter of an inch thick. They were closely packed and felt like beans in a bag. They were not tender. The whole mass formed on each side an elevation about one and a half inches across and one inch high. The symmetry was exact. The skin was moveable over the nodules, and the nodules were moveable over the deep fascia. There were also several nodules irregularly placed on the posterior aspect of each forearm. There was a well-marked mitral systolic murmur, unquestionably organic, but there were no signs of any considerable degree of regurgitation. The rhythm was regular, and there was no increase of dulness to the right of the sternum. As regards treatment I advised counter-irritation and the use of a mixture containing potassium iodide, guaiacum, citrate of potassium, and quinine. The patient was seen by me in the end of March, 1896. A year later the staff-surgeon under whose care he had remained wrote to me as follows: "The man with rheumatic nodules is well and hearty, barring the bruit, which remains, but is not worse. The fibromata were removed where they were giving trouble from their size, and there is no recurrence."

As far as my knowledge goes, this case is unique in the literature of the subject of subcutaneous rheumatic nodules. These bodies occur chiefly in children as part of an attack of acute articular rheumatism, and are usually associated with grave cardiac lesions. Newton Pitt[1] speaks of large, persistent, subcutaneous fibrous nodules associated with arthritis deformans. The evidence of endocarditis in the case I have described led me, however, notwithstanding the anomalous course of the nodules, to regard them as a true rheumatic product. That "rheumatism" can lead to the formation of bodies that deserve the name of "fibromata," and require a surgical operation for their removal, has not, I think, hitherto been recognised.

Nagasaki, Japan.

A CASE OF INSOLATION ACCOMPANIED BY HEMIPLEGIA.

BY ARTHUR F. MESSITER, M.R.C.S. ENG., L.R.C.P. LOND.

ON July 20th, 1896, a healthy boy, aged four years, was out of doors with his father nearly all day long under a burning sun. In the evening the boy "did not seem well," and on the following day he complained of headache. On the 22nd I saw him for the first time. He was drowsy and complained of headache. The temperature was 104° F., the pulse was 120, and the respiration was 18. The tongue was furred; there was no vomiting. Cardiac and pulmonary auscultation revealed nothing abnormal; no abdominal tumidity or tenderness was present. No albumin or sugar was detected in the urine. No joint swelling or pain was present and no scratch or wound was to be found. I ordered three grains of calomel to be administered. On the 23rd the bowels had not acted. The patient was semi-comatose, with a temperature of 104°. An enema was administered with a satisfactory result. On the 24th he was comatose, the temperature being 104·5°. Left facial paralysis was present. The left arm and leg did not respond to stimuli so strongly as the right limbs. During the day the temperature rose to 105·8°, but fell to 103° after the application of an ice-bag to the occiput and the nape of the neck. Nutrient suppositories and enemata of peptonised milk were given. On the 25th and 26th the patient was still comatose; he was breathing quietly, the pulse ranging from 100 to 120 and the temperature from 102° to 103°, rising to 105° on two occasions when the ice-bag became warm or was removed. The bowels and bladder were emptied involuntarily. Rectal feeding was continued as usual. The pupils were neither dilated nor contracted. On the 27th the temperature was 99°. Consciousness was evidently returning. On the 28th the patient was conscious to the extent of speaking intelligently but indistinctly. Owing to his return to consciousness the facial paralysis was seen to be well marked. The eye could be closed with difficulty; the leg could not be moved at all, and the arm only slightly. I was unable to examine the discs for another week owing to his fractious condition; they were normal, and there was no obvious retinal change. Six months elapsed before all traces of paralysis disappeared, and even now he is occasionally noticed to be sleeping with one eye open. He is now (eleven months subsequently to the time of the illness) quite strong mentally and physically.

This case is interesting on account of (1) the gradual onset, (2) the absence of respiratory disturbance, and (3) the occurrence of hemiplegia. Hemiplegia as a complication of heat-stroke must be extremely rare, as I am unable to find any record of it. Dr. Hilton Fagge mentions the case of a sailor who suffered from sunstroke. He was unconscious for some hours, had aphasia for a month, and right hemiplegia for some considerable time. Four years afterwards this man was admitted into hospital suffering from renal dropsy, and died. At the necropsy the arachnoid was seen to be opaque and marked with white spots, and there was an excess of

Hosted by Google

fluid in the brain; the vessels at the base, also, were much diseased. The hemiplegia was, therefore, probably, as Dr. Hilton Fagge points out, an accidental complication depending on pre-existing disease. Surgeon-General Maclean, a man of exceptionally wide Indian experience, in his "Diseases of Tropical Climates" distinctly states that he never saw hemiplegia follow directly on sunstroke.

Epworth, Doncaster.

AN ANENCEPHALOUS MONSTER.

BY SANDERSON MELLOR, L.R.C.P. & L.R.C.S. EDIN., L.F.P.S. GLASG.

A PERFECTLY healthy and comparatively young woman engaged me in the beginning of the present year to attend her in her eighth confinement. My first visit on that occasion was at about 8 P.M. The os was nearly fully dilated; the pains were long and very strong. Through the membranes I felt an uneven, irregular, softish mass, but no bony protuberance of any description. I was told she had been walking about the room since 9 P.M. the previous day. She was becoming exhausted from want of sleep, so I gave her thirty minims of tincture of opium and left her. I was sent for again at 10 o'clock the next morning. Meantime she had dozed for about one and a half hours. The membranes had ruptured and were projecting through the os. I felt something which I likened to the "rim of a cup." She was so worn out that I applied the forceps. Time after time, although the instruments locked, did they slip off. Meantime the fœtus was descending until this irregular mass projected from the vagina. I grasped it with both hands, but finding it impossible to deliver with traction I obtained a piece of "clothes line" and fixing it round the neck, pulled with such force that I thought the head must separate from the body. When the fœtus came away the obstruction was found to be due to the unusual development of the shoulders and upper part of the chest. The head was peculiar. It looked as if it had been arrested in growth from above the orbital ridges in front, and from the level of the protuberance behind. The scalp was intact, the top of the head was quite flat, and the soft pulpy brain could be easily felt. The eyes were extraordinarily large and the eyeballs protruding. The nose was flattened on the face and very broad below. The mouth would not admit the little finger, and the lips were very thick. The spinal column appeared intact. All her previous children were well developed, her sixth and seventh confinements being unusually prolonged. No chloroform was given, and she quickly recovered.

West Malling.

THE NORTH-WEST LONDON HOSPITAL.—The eighteenth annual report of this institution reveals the satisfactory and unwonted fact that not only is the hospital free from debt, but that at the beginning of the year it had a balance in hand of over £2000. The sphere of its work is the somewhat dismal region of Kentish Town, which, if not so poverty-stricken as parts of Westminster or Kensington, yet contains an enormous population to whom the struggle for a respectable existence is very real. During 1896 there were 578 in-patients, as against 683 in 1895, and 17,800 new out-patients, as against 21,227. The decrease in the number of the latter is notable and satisfactory. The hospital is undoubtedly a necessity for the district it serves, and we hope that its satisfactory financial conditions will continue.

WIGAN MEDICAL SOCIETY.—A meeting of the above society was held on June 3rd, the President, Mr. C. T. Street, being in the chair.—The President read his address on the Refusal of Food and Feeding.—A discussion followed, in which Mr. Graham, Dr. R. P. White, Mr. Brady, Mr. Monks, Dr. Rees, Dr. Blair, Dr. Milroy, and Mr. Macdonald took part.—Mr. Street replied.—A cordial vote of thanks was accorded to Mr. Street for his interesting address.—Dr. Benson showed a Radiograph of a Coin Impacted in the Œsophagus, taken by Mr. Thurstan Holland, of Liverpool. He related notes of the case, described the method of removal of the coin (after being lodged for nearly six months), and exhibited it. The child was now quite well.—A discussion ensued, Mr. Brady, Dr. Rees, Mr. White, Mr. Graham, Mr. Monks, Dr. Blair, Dr. Milroy, and the President taking part in it.—Dr. Benson replied.

UNIVERSITY COLLEGE HOSPITAL.

THREE CASES OF STRANGULATED OBTURATOR HERNIA.

(Under the care of Mr. RICKMAN GODLEE.)

A CASE of obturator hernia was first described by Arnaud; Duverney also noticed its occurrence, but the first clear account of this rare condition was given by Garengeot in the early part of the last century. The frequency with which cases of strangulated obturator hernia end fatally is due in part to the difficulty in diagnosis and in part to the difficulty in treatment. The signs of an obturator hernia are very obscure; the pain in the thigh and knee due to pressure on the obturator nerve and the swelling on the inner side of the thigh are very suggestive when they are present, but, unfortunately, they are very frequently absent. The signs of intestinal obstruction resulting from strangulation of the included bowel are often not at all well marked, and this is probably because the hernia is really in many cases a partial enterocele or Richter's hernia, and the absence of severe symptoms may also account for the delay in applying for treatment. Apparently the small intestine is the most frequent viscus in the sac, but the presence of the right ovary and Fallopian tube has been recorded.[1] As to the treatment to be adopted opinions differ greatly. If the intestine is still viable a good result may follow either a local incision or a laparotomy, but if it be gangrenous the chances of recovery after either operation are very slight. In THE LANCET of last year[2] we recorded a case of bilateral strangulated obturator hernia, in which Mr. W. Anderson successfully operated on both sides by an incision through the pectineus muscle. Mr. W. H. Bennett has published[3] a very interesting case of this form of hernia occurring in a woman seventy-eight years old; he performed laparotomy four days after signs of obstruction commenced and the patient recovered. For the notes of the cases we are indebted to Mr. Douglas Drew, the surgical registrar.

CASE 1.—A woman, aged seventy-four years, was admitted to the hospital on Dec. 11th, 1895. On the 3rd she had been seized with pain in the abdomen, and from that date until admission no motion or flatus was passed, in spite of repeated enemata. She looked older than her stated age and was extremely emaciated. An examination of the abdomen was made shortly after admission—i.e., on the eighth day after the onset of the symptoms. Slight vermicular movement of the intestine was noted, the abdomen was quite flaccid, and nothing abnormal could be made out beyond a small inguinal hernia on the right side, which was readily reducible. A large enema was administered without result, and on the following morning it was repeated without effect. At first it was decided to leave the patient alone, as any operation seemed out of the question; but as her general condition did not get worse, and, if anything, rather improved, though the abdomen became slightly more distended, and she vomited twice, on the second day an exploratory laparotomy was decided upon and performed through an incision in the right iliac region. On opening the peritoneum small intestine presented, and was of a deep red colour and slightly distended. The coil was traced downwards and was found to be adherent in the pelvis. Gentle traction was made upon it and it became loose. On drawing it into the wound it was found to have ruptured transversely, and was in a sloughy condition. It contained solid fæces, some of which escaped into the peritoneum. A second perforation was found three inches lower down. The damaged bowel was clamped, and four inches were excised. The mesenteric vessels were

Hosted by Google

ligatured, and the ends of the bowel were then secured by continuous silk suture to the edges of the wound, a Paul's tube being inserted into the upper end of the bowel. The patient only survived the operation a few hours.

Necropsy.—At the post-mortem examination signs of early peritonitis were visible. The pelvic peritoneum was injected, and around the right obturator foramen it was almost gangrenous. The tip of the finger could be inserted into the obturator foramen.

CASE 2.—A woman, aged forty-seven years, was admitted into the hospital under the care of Dr. Ringer on March 6th, 1896. The following history was obtained. Eight days previously she was seized with sharp pain in the right groin, which made her feel very faint and was at once followed by vomiting. The vomiting recurred several times the following day and continued until admission. The bowels had not acted after the onset of the pain, but flatus was passed shortly after the onset of the symptoms. She was the subject of chronic constipation, and twelve years previously had had an attack of gall-stones. On admission she did not look very ill. The pulse was 100 and of good quality, the temperature was 96° F., the tongue was red but clear, and the breath was offensive. The abdomen was slightly distended and peristaltic movements were obvious. There was no tenderness, and nothing abnormal could be felt. The rectum was empty, and per vaginam a little tenderness was present on the right side. For two days the treatment consisted of cutting off all nourishment by the mouth, giving enemata and nutrient injections and opium. On the third day, as the bowels had not acted and the abdomen was becoming more distended and vomiting had recurred, exploration of the abdomen was decided upon, and was performed through a median incision below the umbilicus. On opening the peritoneum congested coils of intestine presented. On digital examination the intestine was found adherent around the right obturator foramen, and a small piece had entered the foramen and could not be withdrawn by gentle traction. A hernia knife was passed down and the constriction divided and the bowel drawn up into the wound, when it was found to have given way just above the hernia, some fæces escaping into the peritoneum. On examination a pouch about half an inch in length projected from the side of the bowel; it was deeply congested, but not gangrenous, and had evidently been constricted in the foramen. The peritoneum was cleansed by sponging and the bowel was drawn into the wound and sutured, the opening in it being enlarged. The patient sank a few hours after the operation.

Necropsy.—At the post-mortem examination the coils of small intestine were greatly distended and inflamed, and some lymph was present in the pelvis. The strangulated portion of the bowel was eighteen inches from the cæcum; below the constriction the bowel was collapsed. The right obturator foramen admitted the tip of the little finger, and a hernial sac measuring one and a half inches extended between the obturator externus and the adductor muscles; it was black and gangrenous. The obturator vessels and nerve were situated below and to the outer side. A small piece of omentum was adherent within the sac.

CASE 3.—A woman, aged fifty-nine years, was admitted into the hospital on Dec. 8th, 1896. On Nov. 30th, while sitting in front of the fire, she was seized with severe pain in the right knee, and this was soon followed by abdominal pain. Vomiting occurred soon after the onset of the pain, and persisted throughout. The bowels had not acted, except on the second day after the onset of the illness. On admission the abdomen was found to be much distended, and coils of intestine were visible. There was some tenderness in the right groin, and a small rounded mass could be made out just below the inner part of Poupart's ligament. An operation was at once performed; the incision was situated over the inner part of Scarpa's triangle, and extended from just above Poupart's ligament downwards for three inches, and was placed internal to the saphenous vein. On opening the deep fascia the adductor longus was exposed, and the interval between this muscle and the pectineus defined and opened up. The edges of the muscles were retracted and some fibres of the adductor brevis divided. The superficial part of the obturator nerve was then seen lying over the sac, the latter having come through between the fibres of the obturator externus. The sac was opened; and as the bowel did not appear to be damaged beyond being somewhat congested it was reduced by gentle pressure, the sac being ligatured and cut away. The following morning the patient appeared to be doing well, but in the afternoon she complained of abdominal pain, and shortly afterwards became collapsed and died.

Necropsy.—On opening the abdomen well-marked signs of general peritonitis were present. The small intestines were distended and injected, and here and there flakes of lymph were seen. The omentum was adherent to the right side of the pubis. On separating it, the small intestine was found adherent around the obturator foramen, the part above the seat of constriction was distended and injected, and that below was pale and collapsed. On separating the adherent intestine the strangulated part gave way along the line of constriction for about half an inch. The constriction surrounded a prominent knuckle and involved a little more than half of the circumference; the strangulated portion was of a deep red colour, and did not appear to be gangrenous except where it had given way. The specimen was removed and the vessels were injected. Viewed from the front there was a small protrusion of peritoneum through the somewhat enlarged foramen. The artery was situated below the sac, and was dividing into branches, some of which came out on the inner side and others through the membrane. The two branches of the obturator nerve lay to the outer side. Viewed from the inside the neck of the sac was small, and in depth measured about half an inch. Immediately below it lay the Fallopian tube and broad ligament, the former being drawn down by the broad ligament. On turning the Fallopian tube upwards a second smaller pouch was found, formed by a protrusion of the broad ligament, and was firmly fixed in the sac. The bowel had been protruded through the upper of these two pouches.

Remarks by Mr. RICKMAN GODLEE.—It seems well to record these three cases, though they were all unsuccessful. It will be observed that they were all admitted to the hospital eight days after the onset of the symptoms, and therefore were all very unfavourable ones for treatment. The first patient was so very old and emaciated that she looked more dead than alive, and I thought it was kindest to leave her alone; but when it was found that she remained exactly in the same condition for more than a day I decided to give her a chance. The condition of things was easily made out, and there was no difficulty about the surgical procedure adopted. The operation was delayed in the second case because no diagnosis was possible, and the effect of enemata had not been tried. The third case was easily diagnosed and was operated upon at once. The great ease with which the bowel ruptured in the first two cases, and the difficulty of satisfactorily dividing the stricture from above, determined me to operate on the next case that occurred from outside. The operation in this case was perfectly simple as the patient was thin. Here, as in the other cases, a small part only of the bowel was included in the hernia, and, as in them, was after the lapse of so many days but little altered in appearance. The gentlest pressure of the tip of the finger on the minute knuckle of bowel was enough to make it return into the abdomen, and it seemed fair to hope that the part which had been opposite the neck of the sac might not be gangrenous, but the event showed that this was not the case. It was, of course, impossible to pull the bowel down and ascertain the actual condition of things. I cannot help thinking that if the patient be seen early the right course to pursue is to operate from outside. But if I should meet with another case that has lasted so long as these three I intend to do this and to open the abdomen as well. Supposing the diagnosis has been made, I think it would be best to perform the operation in Scarpa's triangle first and to open the abdomen afterwards; if the bowel then turned out to be healthy enough the wound might be simply closed; but if there were a patch of gangrene corresponding to the stricture the affected part could be excised or an artificial anus could be made as seemed best under the circumstances. If, on the other hand, the diagnosis were only made during the course of the laparotomy I think it would be wisest to expose the sac in Scarpa's triangle, divide the stricture if necessary, push back the bowel, and then pull it up into the laparotomy wound and examine it. I have now pulled it up into the wound in the same way as in the first two cases on three occasions, and in each the result has been the same—namely, the giving way of the gut at the position of the stricture. In performing the operation from outside there appears to be no danger of wounding the femoral vein if the incision be made sufficiently far internally on to the surface of the pectineus; the femoral sheath and all that it contains is then easily pulled outwards out of the way.

Hosted by Google

As to which direction is the best for making the section in order to divide the stricture it is difficult to lay down any fixed rule, but I think in the majority of cases it will be safest to make it either directly inwards or forwards and inwards. But should any branch of the obturator artery be injured the double operation will probably render it comparatively easy to secure the bleeding point.

ROYAL INFIRMARY, LIVERPOOL.

A CASE OF INTERMITTENT HEMIPLEGIA.

(Under the care of Dr. A. DAVIDSON.)

THE only condition in which transitory recurring attacks of hemiplegia occur is uræmia, as in a case recorded by Boinet [1] in which a man, aged thirty-seven years, suffered from five attacks of uræmia within a short time; in the first two there were only localised convulsions, in the third he had unilateral convulsions followed by hemiplegia, and in the fourth and fifth attacks the hemiplegia occurred alone. In the following case there seems no reason to suspect a renal origin of the hemiplegia. Dr. Davidson's explanation is extremely ingenious, and is no doubt possible; in its favour is the fact that ultimately the hemiplegia became permanent. Should the case finally prove fatal, it is very desirable that the local lesion should be early and carefully examined.

A watchman, aged seventy-three years, was admitted into ward 10 of the Royal Infirmary, Liverpool, under the care of Dr. Davidson on Jan. 18th, 1897, suffering from left hemiplegia. He had worked on a farm till fifteen years previously, when he came to Liverpool. He always enjoyed very good health. On the afternoon of Jan. 18th, after arranging his lamps, he sat down in his sentry-box before the fire. On trying to get up again he found himself unable to do so; so he called for assistance. Two policeman raised him; he was unable to stand alone, but had no loss of consciousness, either then or at any time. An ambulance was procured and he was brought to the hospital at 6·30 P.M. On admission he was quite conscious. His left side was completely paralysed. The pupils were equal and reacted to light; the upper part of the face was partially weakened on the left side; at the lower part the mouth was drawn to the right side, the articulation was imperfect and mumbling, and the tongue was protruded slightly to the left side. The left arm and leg were totally paralysed. Sensation seemed everywhere normal. The pulse was 76 and regular. Two hours after admission he had regained complete power in his face and limbs. He passed urine without trouble. He seemed somewhat excited, but otherwise was quite well. During the night he had four or five hemiplegic attacks similar to the first, each lasting from about fifteen to thirty minutes, all without loss of consciousness. On the morning of the 19th he was free from any sign of paralysis of the face, arm, or leg. The dynamometer showed the grasp of the right hand as 50 and the left as 40. As regards his general condition, he was a hale-looking old man; the tongue was coated, the teeth were very defective, the appetite was good, the pulse was 76 and regular, the arteries were thickened and tortuous, the heart-sounds were normal; the chest was emphysematous, there were slight cough and expectoration, and the urine was normal. At 12.30 P.M. he was again found to have complete paralysis of the face, arm, and leg of the left side. About 1.15 P.M. Dr. Davidson saw him for the first time. He had paralysis of the left side. He could wrinkle the brow on both sides, and close both eyelids together, but he could not close the left eyelid without the right. The left side of the mouth was immobile. Articulation was only slightly affected. The left arm was quite powerless. In the left leg there was only a very slight ability to move the hip and knee. Sensation was normal. While he was still under examination (1.45 P.M.) he drew Dr. Davidson's attention to the gradual return of power in his left hand, and presently the paralysis entirely disappeared. He could now close the left eye independently as well as the right. He was ordered to have a dose of calomel, and eight grains of bromide of potassium three times a day. During the next twenty-four hours several alternations of paralysis and recovery took place, but the remissions by degrees became shorter and slighter. On the night of Jan. 20th the hemiplegia became almost permanent, and remained so till his removal from the hospital by his friends on the 28th.

Remarks by Dr. DAVIDSON.—I have seen the patient twice since at his own home, the last time in the beginning of June. He remains in good general health and spirits. The pulse is 72 and regular. The arm is completely paralysed, he can just move the fingers; there is no rigidity and no pain except in the shoulder (rheumatic); the leg and face are rather better. He can lift the leg off the bed. There is some tenderness in the thigh. The tongue is protruded straight. The bladder is normal.

This interesting case is unique so far as my experience and reading go. When I related the history lately at a meeting of the Liverpool Medical Society, one of the members, Dr. Kennan, referred to a case of a man with complete left hemiplegia, which disappeared in a quarter of an hour only to return half an hour later and become permanent. One used to hear of "spasm" of cerebral arteries as being a possible cause of temporary hemiplegia; and one can conceive such an explanation reasonable in cases of uræmia, &c. There was nothing to point to that here, or to embolism from the valves of the heart. The explanation which I gave at the time and still adhere to is that a thrombus in the atheromatous cerebral artery became partially detached, and flapped to and fro in the current of blood, occasionally blocking the artery and occasionally leaving the current free. Or, if it was entirely detached and arrested at the next bifurcation of the artery, it might there sway to and fro like a ball valve, until by continued growth it became fixed and a permanent block of the vessel resulted.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Filaria Loa.—Sympathetic Ophthalmitis.—Blindness following Blows on the Head.—Exhibition of Cases.

AN ordinary meeting of this society was held on June 10th, Mr. E. NETTLESHIP, President, being in the chair.

Dr. ARGYLL ROBERTSON gave an account of Filaria Loa in continuation of a description furnished by him two years previously in the same patient, who had returned to Old Calabar and immediately suffered a return of her former symptoms. There were itching behind the eyes and swellings in the arms, as described by Miss Kingsley as almost universal in the Gaboon district. On one occasion at night the patient felt a bite in the flank, and forthwith extracted a portion of a worm. Movement of a similar parasite was felt under the conjunctiva, and twice incisions were made in the knuckles in quest of one felt moving to and from the arm. Sandflies and mosquitos were sent home and examined by Dr. Robertson and Dr. Manson with a view to finding the intermediate form, but without success. Finally, the patient herself returned, invalided with dysentery and anæmia. Nausea and headache occurred while the parasites were moving about, associated with puffy swellings in the arms. All parts of the body were affected, but especially the scalp; as recently as May 15th, 1897, the parasite was perceived moving near the umbilicus, but could not be secured. The blood, excreta, saliva, and nasal mucus were carefully examined for embryos, but without success. Since the former account of this case was given two instances had been described on the continent, and two were at present under the treatment of Dr. Manson.

Mr. RICHARDSON CROSS read a paper on Sympathetic Ophthalmitis, especially in connexion with Mules's operation of evisceration. He cited several instances in which sympathetic irritation, or ophthalmitis, had followed the operation, the proportion being as high, he said, as 13 per cent. One patient in particular was under treatment of the most watchful and sustained kind for seven months before he happily recovered. In another a black mass at one corner of the stump was mistaken for melanotic sarcoma, but on closer examination proved to be an artificial vitreous of silver which had been inserted ten years previously. Many cases certainly appeared to do well for a time, but sooner or later trouble generally supervened.—Mr. ADAMS FROST referred to the fact that there was a committee at present

Hosted by Google

considering the whole subject of sympathetic ophthalmitis. He thought unsuccessful cases—that is, cases in which sympathetic trouble followed—were often those in which delay had occurred between the original injury and the evisceration, giving time for infection to take place before the operation, or else those in which a fistula persisted leaving the channels open for subsequent infection. He cited twelve cases of four years' standing, and others of eight and nine years, without any after-trouble; in one there developed nystagmus in the sound eye after five years, and this was perfectly represented in the artificial one.—Mr. BICKERTON declared his experience in favour of Mules's operation, and referred to published and collected cases, which showed a percentage of 15 sympathetic ophthalmitis after complete enucleation. (These, however, were shown to be picked and more than ordinarily severe cases collected from the point of view of sympathetic ophthalmitis, and not representing the true proportion of the disease following simple enucleation.) He cited a case in which, though the disturbance occurred, it subsided in about ten days, the eye recovering perfectly.—Mr. SNELL questioned whether sympathetic ophthalmitis occurred as frequently as formerly. His experience led him to believe it did not, and he attributed the improvement to the greater care exercised. Though dealing with many cases of injury he enucleated fewer eyes. He thought the percentage of subsequent sympathetic change indicated in the paper a very high one.—Mr. CRITCHETT, Dr. ARGYLL ROBERTSON, and the PRESIDENT all spoke as to the rarity of sympathetic ophthalmitis after complete enucleation. The President said it was an important question in pathology whether the disease occurred in a less intense form after Mules's operation or not.—Mr. TREACHER COLLINS inquired whether the stumps had been carefully examined after removal to see if evisceration had been complete. (Of this there was no record.)—Mr. RICHARDSON CROSS, in reply, said he was sure many cases occurred after Mules's operation even with the strictest antiseptic precautions and often after many years. He preferred enucleation.

Mr. S. SNELL read a paper on Blindness following Blows on the Head. Loss of vision was attributed to fracture extending into the foramen rotundum, and was the result generally of injuries to the front of the cranium; but Mr. Snell showed that a similar condition not infrequently resulted from injuries to any part, and cited several instances of blows on different parts of the skull which led to immediate loss of vision in this way.—Mr. BICKERTON spoke of the remote as well as the immediate effects of injury to the head in producing blindness, and referred to the interest connected with cycling accidents and insurance. He mentioned the case of one man who compounded with an insurance company for £50 as compensation for such an accident which later led to complete blindness.—Mr. LINDSAY JOHNSON spoke of the effects of injury to the head in animals followed by blindness, and quoted instances in a crane, a leopard, a bear, and a kangaroo in which he had subsequently observed white atrophy of the disc.—Mr. CRITCHETT mentioned an instance in which a heavy blow above the nose was followed by a reduction of vision to $\frac{2}{70}$, and subsequently to bare perception of light. The case was the subject of a lawsuit. In a case recorded at the time in "Holmes's System of Surgery" the opinion was expressed that loss of vision might follow late from such an injury.—The PRESIDENT discriminated between immediate and remote loss of vision in connexion with head injuries; of the first there could be no doubt, but the second was liable to great difference of opinion and interpretation.

The following cases were shown:—

Mr. J. R. LUNN: Bilateral Facial Palsy, Deafness, and Ulceration of the Corneæ.

Mr. LUNN and Mr. C. D. MARSHALL: Foreign Bodies embedded in the Orbit.

EDINBURGH OBSTETRICAL SOCIETY.

Report on Specimen—Culture, Diagnosis, and Serum Treatment of Puerperal Fever—Morphology of the Vaginal Segment of the Genital Tract.

A meeting of this socieiy was held on June 9th, Dr. ALEXANDER BALLANTYNE, President, being in the chair.

The specimen shown at last meeting by Dr. KYNOCH was reported upon by Dr. HART, Dr. HAULTAIN, and Dr. BARBOUR. They found it very difficult to say whether it was a case of interstitial gestation or of rupture of the pregnant uterus. The clinical history suggested the former, while the situation of the rent, the marked hypertrophy of the uterine wall, and the appearance of the Fallopian tube were in favour of the latter view.

Dr. F. W. N. HAULTAIN read a paper on the Culture, Diagnosis, and Serum Treatment of Puerperal Fever. He gave detailed accounts of three cases. The first was a primipara where help was needed in the labour by the application of low forceps. The puerperium for the first ten days was normal, except that the strength was not regained with the usual rapidity. On the twelfth day she fainted on attempting to rise, and for a fortnight her pulse was quick and there was a rise of temperature to about 100° F. On the twenty-sixth day she first complained of severe pain and swelling in the right thigh, this rapidly passed off; four days afterwards pain occurred in the left thigh and calf, associated with considerable swelling and severe constitutional symptoms; vomiting, sweating, and faintness. Dr. Haultain then saw her. Pelvic examination revealed nothing abnormal except a subinvoluted uterus and a slight swelling in the left broad ligament. The lochia were a little offensive, and a culture was made of the discharge from the interior of the cervical canal; one was also made from the blood drawn from the finger. The former showed a typical pure culture of the Löffler bacillus; 10 c.c. of the diphtheritic antitoxin were injected with marked beneficial results. On two successive days a similar quantity of serum was injected as the temperature again slowly rose. After the third dose the temperature fell to normal and she had an uninterrupted recovery. No case of diphtheria was present in the neighbourhood and the attending practitioner had not seen a case of diphtheria for some weeks previously, but the drains were found to be in an insanitary state. The second case showed marked signs of fever forty-eight hours after the labour. The medical man had used intra-uterine douches, but without benefit. Dr. Haultain saw her on the fifth day. She then showed signs of marked septic infection, the face had a leaden appearance, and there were erythematous patches on the abdomen. A culture of the discharge, similarly taken, was again made, and examination showed a mixed growth of streptococcus and bacillus coli. Anti-streptococcic serum (10 c.c.) was injected, followed by a similar quantity the next day, and 30 c.c. on the third day, but no beneficial effect resulted. The patient developed an intractable diarrhœa; her left knee-joint became extremely painful; pulmonary complications and parotitis set in, and she died on the tenth day. A culture was made from the blood of the finger twenty hours before death, and a pure growth of the bacillus coli was found, which from its reactions was found to be extremely active and virulent. The patient was a coachman's wife and was confined in a room immediately above the stable. The third case had been attended by an unskilled woman, and showed signs of fever on the third day. Dr. Haultain saw her four days afterwards. The vaginal discharge was offensive. The culture showed many streptococci. Anti-streptococcic serum (10 c.c.) was injected; the uterus was washed out with a 1 in 40 carbolic lotion and packed with gauze soaked in the antitoxin. On the next day a further 10 c.c. were injected. The temperature fell on both occasions. No further rise of temperature occurred, though the cervical discharge showed many streptococci. The uterus was washed out on the two succeeding days, and further examination showed the discharge to be free from septic organisms. On reviewing the cases, the first one was evidently a case of intra-uterine diphtheria, and the diagnosis would have been impossible except for the bacteriological examination. The second case showed features of interest in the presence of mixed infection in the culture from the cervix and in the pure culture of the bacillus coli from the blood. Clinically, the violent diarrhœa, the erythematous patches and the absolute inefficiency of the antistreptococcic serum, were of value. The third case was one of those simple cases of toxin poisoning which usually yield to antiseptic intra-uterine douching, the focus of the disease being thus removed. Still it must be noted that intra-uterine douching had almost no effect until combined with the serum treatment. In all cases of puerperal fever the culture method of diagnosis was much to be preferred to all others. The microscope alone was helpful, but no idea could be obtained of the vitality or virulence of the organisms. In the prognosis, a

Hosted by Google

mixture of germ infection in a case was of serious import as there was then increased virulence. The treatment of these cases could only be scientifically met by previous culture diagnosis to detect which toxin was the main cause of the disease. For preventive treatment Dr. Haultain strongly urged the necessity of using a douche after labour in every case, and recommended 1 in 40 carbolic lotion, which had been found more efficient in experimental research than sublimate lotion. Dr. HART, Dr. MILNE MURRAY, Dr. BARBOUR, Dr. MCVAIL, Dr. KEPPIE PATERSON, Dr. JARDINE, and others took part in the discussion, and in reply as to the method in use of obtaining cultures, Dr. HAULTAIN stated that he passed a Fergusson's speculum and exposed the cervix. A platinum wire, previously rendered aseptic by heating in a flame, was passed into the cervical canal and some discharge obtained on it. This was then dipped into the agar in a prepared test-tube, the tube at the time being held bottom upwards to prevent dust and germs from falling into it. A plug was inserted and the tube transmitted to the Laboratory of the Royal College of Physicians of Edinburgh.

Dr. BERRY HART then read a paper on the Morphology of the Vaginal Segment of the Genital Tract. The conclusions arrived at were as follows:—1. The human vagina is derived from the ducts of Müller only in its upper two-thirds; the lower third is due to a blending of the upper portion of the uro-genital sinus of the Wolffian ducts. 2. The hymen is formed between the third and fourth months of fœtal life and is due to the development of two bulbs of epithelium from the lower ends of the Wolffian ducts. These coalesce, break down in the centre, and with an upward involution from the uro-genital sinus form the hymeneal opening. 3. The "calliculus seminalis" of man is the analogue of the lower third of the vagina. 4. In the marsupials the lateral canals are the persistent Wolffian element, and the central blind pouch is the Müllerian element.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A Case of Charcot's Disease.

A MEETING of this section was held on May 21st, the President, Dr. G. F. DUFFEY, being in the chair.

Mr. CONOLLY NORMAN related a case of Charcot's Disease, exhibited the patient, and also exhibited skiagrams showing the condition of the bones.—Professor BENNETT said he thought that the point was the nature of the change in the joints. Was the case to be regarded as a variation of chronic articular rheumatism or a distinct disease? His knowledge of Charcot's disease was very small, he said, having only seen one specimen in Dublin. He had seen Charcot's specimens exhibited in London at the late Congress. The destruction of bone was specially great in Charcot's disease—much greater than in chronic articular rheumatism. He was inclined to think that the disease was essentially the same as chronic articular rheumatism in pathological detail, except that there was a great deal of effusion. As a rule, chronic articular rheumatism was in this country attended with effusion, but not so in France, as proved by the French term applied to the disease—*arthrite sèche*.—Dr. FINNY said that in his limited experience of Charcot's disease he had not found the cases quite the same as Mr. Norman's. The effusion in the joints which he had seen was very much greater, and the backward movement of the leg was one of the remarkable features. He had not himself found in neuritic cases that motility in the joints to which Mr. Norman had referred. He was very much in a difficulty as to the disease being tabetic, because of the mental condition of the patient, and it was not easy to test for knee-jerk. If it was a case of tabes it was interesting to note that the patient was unaffected in the upper limbs; of course, the disease might be limited to the lower extremities for a long time, but there seemed to be none of the other occasional symptoms. The case was one which, he was sure, must remain for a certain time in an unknown category.—Mr. NORMAN, in reply, said that everyone was familiar with the doctrine that Charcot's disease was merely a variety of chronic articular rheumatism. He thought, perhaps, that a truer view to take was that some nervous disorder with which they were at present unfamiliar was associated with chronic articular rheumatism. With regard to the absence of backward displacement to which Dr. Finny had referred, he thought it possible that the condition of disturbance in the joints had been arrested before the customary destruction of the posterior ligaments. He could not say how long the condition had lasted, save that it did not exist in 1890, but did in 1896, and according to the patient's own statement the disease would have commenced in 1895. The only sign of tabes which she exhibited—excepting the condition of her legs—was the Argyll-Robertson phenomenon. There was a great deal of anæsthesia still in her legs, which, of course, was in favour of alcoholic neuritis. He thought it likely that the condition was still undescribed.

Dr. KNOTT read a paper on a Fatal Case of Alcoholism.

Reviews and Notices of Books.

An American Text-book of Physiology. Edited by W. H. HOWELL, M.D., Professor of Physiology in the Johns Hopkins University, Baltimore. Philadelphia: W. B. Saunders. 1896. Pp. 1052.

IT is almost a common-place to remark that physiology has nowadays grown to such an extent that no one man can be perfectly conversant with all its branches. Most text-books written by a single individual are distinguished by special excellence in one particular branch of the subject. The present volume constitutes practically a new departure in physiological text-books on the lines which have already proved successful in medicine and surgery in the "Systems" which have appeared on those subjects. It is written by the leading physiologists of America, each undertaking that branch with which he has special acquaintance. The merits and disadvantages of this plan have been discussed often enough; the results in this case are excellent, and Professor Howell is to be congratulated on the editorship of a most valuable and comprehensive series of monographs. The wise encouragement afforded to pure science in America is bearing fruit in many ways, and in none more conspicuously than in the excellent text-books which from time to time appear in that country. This book professes to be an elementary text-book on physiology; its somewhat alarming bulk may well terrify the student, but its value as a work of reference for the physician or pathologist is very great.

Professor Howell himself contributes a thoughtful and deeply interesting introductory chapter, in which, while admitting the physico-chemical nature of the majority of vital processes, he shows himself fully alive to the difficulties of a purely material explanation of the phenomena of life. From the same pen are the articles on Secretion, on the Chemistry of Digestion and Nutrition, on the Movements of the Alimentary Canal, Bladder, and Ureter, and on the Blood and Lymph, all of which show a deep and thorough acquaintance with the subjects in question and a remarkably lucid power of exposition. Dr. Warren P. Lombard, of Michigan, writes on the General Physiology of Muscle and Nerve and on the Physiology of the Special Muscular Mechanisms—articles which are of great value and clearness. The subject of the circulation is admirably dealt with by Professor Curtis, of Columbia University, and Dr. Porter, of Harvard. Professor Reichert, of Pennsylvania, treats of Respiration and Animal Heat in thorough and masterly articles. Professor Donaldson, of Chicago, one of the greatest authorities on neurology, writes on the Physiology of the Central Nervous System in a peculiarly admirable article, which should form for many years a standard contribution to the subject. Vision is dealt with by Professor Bowditch, of Harvard, and the other special senses by Professor Sewall, of Denver. Dr. Lee, of Columbia University, treats of Reproduction, while Professor Graham Lusk, of Yale, contributes the section on Animal Chemistry.

Hosted by Google

The book is excellently printed and well indexed. It is impossible, in the limits of a review of this kind, to discuss the several sections of so large and important a work in adequate detail, and we have preferred not to attempt it, though we have tested the book by daily use. We can commend it most heartily, not only to all students of physiology, but to every physician and pathologist as a valuable and comprehensive work of reference, written by men who are of eminent authority in their own special subjects.

Twentieth Century Practice: an International Cyclopædia of Modern Medical Science. Edited by THOMAS L. STEDMAN, M.D., New York City. Vol. VII. Diseases of the Respiratory Organs and Blood, and Functional Sexual Disorders. London: Sampson Low, Marston, and Co. 1896.

THIS is a uniformly good volume. Every article is full and clear and practical. No better idea could be obtained of the deservedly high position taken by American writers in medicine than by reading the seven American contributions to this volume. Dr. Herbert Whitney, of Denver, devotes 126 pages to a thorough account of Diseases of the Pleura. He is particularly happy in his description of the mechanical conditions at play in pleural effusion and pneumothorax. In discussing displacement of the heart and displacement of the mediastinum in comparatively slight effusions he writes: "The mediastinum, too, cannot remain unaffected. Usually under the equal negative pressure of both pleural cavities, it is now subjected to an increased relative pressure upon the side containing fluid, and much more slightly in the opposite direction. This fact is of vital importance as explaining the early displacement of the heart which may occur in pleuritic effusion. Certain authors (Powell, Garland) have laid great stress upon the assertion that the heart is not pushed towards the well side by the accumulating fluid, but drawn over by the opposite lung. The point does not appear to be well taken. The mechanism of the displacement is clear; and since it is quite evident that the increased unilateral pressure would compel a movement of the mediastinum independently of the well lung, it can hardly be said to be drawn over by the latter." In contrasting the mobility of the fluid in pneumothorax with its fixity in a case of pleural effusion Dr. Whitney sums up thus: "(1) That very large effusions are immoveable; (2) that moderate effusions do show a slight change after a lapse of several minutes; and (3) that the extent of this change rarely amounts to more than a single intercostal space. As to small effusions statements are meagre. ..... I myself have never been able to detect the slightest change in the position of a small effusion." Dr. Whitney's account of vocal fremitus in pleural effusion is not quite satisfactory. Among the many pitfalls in the diagnosis of pleural effusion, the absence of tactile vocal fremitus remains perhaps the most reliable of guides. There are a few cases where with large effusions tactile vocal fremitus is not lost, but in an overwhelming majority it is absent. "Few signs of effusion are more valuable than absence of tactile vocal fremitus. ..... Still, it is not infallible. ..... In a large effusion fremitus is usually considerably increased over the lung because of its solidified condition" (p. 28). This last sentence is certainly at variance with facts. The various forms of empyema and their treatment could not be better summarised. Dr. Whitney states that pulsating pleurisy is "found only when the empyema is upon the left side." This is, of course, true of the great majority of cases, but there are some exceptions.

Dr. Franz Riegel, of Giessen, amplifies and brings up to date his article on Bronchial Asthma in von Ziemssen's "Cyclopædia of the Practice of Medicine."[1] The most interesting pages are those in which he discusses the method of formation of the Curschmann spirals, tracing them to two factors—(1) the viscidity of mucus; and (2) the "corkscrew-like course" of the fine bronchial tubes as demonstrated by Hoffmann. He adopts Gollasch's theory "that Leyden's crystals are crystalline derivatives of the eosinophile cells," and quotes certain facts which give support to this view. The increase in the number of eosinophile cells during an attack of asthma which has been asserted to exist by some observers is not confirmed by all who have investigated this question. Einthoven's experiments are held by the author to prove definitely that the theory of spasm of the bronchial muscles is correct. Dr. Riegel gives a well-balanced account of the treatment of asthmatic patients. Dr. Fletcher Ingals, of Chicago, contributes a good short chapter on Hay Fever, the greater part of which is devoted to treatment. He illustrates by some diagrams the good effects obtained by cauterisation of the nasal mucous membrane between the attacks. Only eight and a half pages are given to Dr. Main for Diseases of the Mediastinum—obviously a very inadequate space.

The longest and most important chapter in this volume is that on Diseases of the Blood, by Dr. Alfred Stengel, of Philadelphia. It extends over 300 pages and is admirable from beginning to end. Ample descriptions are given of all the methods best suited for thorough examination of the blood, and full accounts of the different abnormal conditions. The use of iron in chlorosis and the method of its action afford a constant source of discussion. Dr. Stengel sharply criticises Bunge's theory "that the iron administered to chlorotic patients proves efficacious only by entering into combination with the sulphuretted hydrogen developed in excess by intestinal putrefaction, and thus permits the ferruginous nucleo-albumin of the food to be absorbed." He brings forward much evidence, some of it new, to show conclusively that Bunge's hypothesis is only very partially if at all true. It has been found "that the administration of sulphide of iron itself proves beneficial in chlorosis; that substances quite as prone to enter into combination with sulphur do not exercise the same influence, while other substances, notably arsenic, and other measures of treatment having no influence upon processes of intestinal putrefaction, do have a beneficial effect. Finally, experimental investigation has shown that there is no evidence at all of intestinal putrefaction in many cases of chlorosis." Dr. Stengel falls back on the somewhat vague but probably true view that "iron acts as a direct stimulant to the hæmopoietic organs" (p. 356). The more unusual "diseases of the blood" are very well described. Dr. Jules Comby, of Paris, has a good article on Rickets. The chapters on the disorders of Menstruation by Dr. Cushing and Dr. Cumston of Boston, and on the Functional Disorders of the Male Sexual Organs by Dr. Charles Allen, of New York, are full of facts and common sense. The last chapter, by Dr. French, of Cincinnati, on the Examination of the Urine, extends over 120 pages and is very thorough. In describing the occurrence of the bacillus tuberculosis in urine some mention should be made of the liability to error produced by the presence of the smegma bacillus, the staining reactions of which are so similar.

The bibliographies throughout are excellent. The volume does great credit to all concerned.

The Procedure in Accident Inquiries and Investigations According to the Law of Scotland. By H. H. BROWN. Edinburgh: T. and T. Clark. 1897. Price 7*s.* 6*d.*

IN this book an endeavour is made to bring into one view the various enactments relating to the subject mentioned in the title. A large number of Acts of Parliament deal, some with one part, some with another, of the matter in question, and Mr. Brown has performed a very useful service to his brother officials and other persons concerned with the

Hosted by Google

administration of the law by collecting these various statutes and grouping them in such a way as to render them mutually illustrative. The book deals with the law of Scotland only; and it is much to be desired that some competent person may supplement the present work by a similar *résumé* of the law and formulas applicable to England and Ireland. Mr. Brown points out with much force that when an accident happens with the suddenness characteristic of such events any loss of time in instituting the necessary investigation is apt to be serious. A book such as he has produced is calculated to have a marked effect in minimising such loss of time; for the various officials who are called upon to conduct such investigations depend much upon one another for notice of material facts, and whatever tends to facilitate the giving of such notices must serve in equal measure to accelerate the progress of investigation.

A mere glance at Mr. Brown's book suffices to show that the course of legislation has resulted in extremely complicated machinery. It is by no means a rule that a scheme which looks complicated on paper must prove unmanageable in working, and having regard to the great variety of the circumstances in which industrial accidents occur we are not disposed to argue for any strictly unified system of investigation. The matter of prime importance is that the inquiry should be entrusted to some competent person on the spot, and this condition can only be satisfied by taking advantage of existing machinery in a manner that is quite incompatible with unity of plan. But this condition makes the need of a text-book such as this volume supplies quite imperative.

The plan of the book is to split up the subject into departments, and accordingly separate chapters are devoted to accidents in mines, in factories, on railways, on board ship, from boiler explosions, from explosive substances, and so forth. This plan is excellent, and the various chapters, being written by a practical man and copiously illustrated with official and other necessary forms, are eminently helpful. Altogether it is a very useful book which may be confidently recommended to procurators fiscal, factory inspectors, certifying surgeons, and others concerned in the investigation of industrial accidents.

LIBRARY TABLE.

Diagnostik der Inneren Krankheiten auf Grund der Heutigen Untersuchungsmethoden. Ein Lehrbuch für Aerzte und Studirende. Von Dr. OSWALD VIERORDT. Funfte verbesserte und vermehrte Auflage. Leipzig: Verlag von F. C. W. Vogel. 1897. Preis 14 Mk. (*Diagnosis of Internal Diseases based on Modern Methods of Examination.* A Text-book for Practitioners and Students. By Dr. OSWALD VIERORDT. Fifth edition, improved and enlarged. Leipzig: F. C. W. Vogel. 1897. Price 14*s.*)—This is a standard work. Its author is the Professor of Medicine at the University of Heidelberg, and the popularity of the text-book is evident from the fact that five editions have been called for within nine years. The systematic manner in which the subjects are treated and the clearness with which the signs and their import are described sufficiently account for this appreciation. That it has been brought up to date is evident from the inclusion in it of details concerning the serum test for typhoid fever, which is admitted by the author to be of very high value. A noteworthy feature of the book is the section devoted to the diagnosis of diseases of the nervous system, introduced by remarks on the topography of the brain, the paths of motion, sensation, and the special senses, and the facts bearing on the locality of lesions. The various disorders are described under the heads of psychical disturbance, sensory and then motor derangements, muscular atrophies, spasm, and contractures. The reflexes are next considered, and then the electrical examination of paralysed muscles. There is a very detailed consideration of aphasic conditions, and a description of the derangements of the various systems in nervous disease. More space might with advantage have been devoted to the use of the ophthalmoscope, which is relegated to an appendix, together with laryngoscopy, rhinoscopy, and otoscopy. The work in its earlier edition was translated into English, and it certainly ranks well in the large and ever-increasing series of books on diagnosis.

Vorlesungen über Allgemeine Pathologie. Von Dr. M. LÖWIT. Erstes Heft. Die Lehre vom Fieber. Jena: Verlag von Gustav Fischer. 1897. Preis 5 mk. (*Lectures on General Pathology.* By Dr. M. LÖWIT. Part I. The Doctrine of Fever. Jena: G. Fischer. 1897. Price 5*s.*)—Whoever undertakes to discuss the subject of fever has a formidable task, for there are few subjects in pathology which have received so much attention, or upon which, in spite of this, there remains so much that is uncertain. Dr. Löwit, the Professor of General and Experimental Pathology at the University of Innsbruck, is well qualified for this work, and in this first instalment of his lectures enters with commendable zeal upon his labours. The reader of these thirteen lectures will find them teeming with information and a wide knowledge of the researches of those who have contributed to the subject. It is clearly shown that the conception of fever means much more than mere increase in body temperature, the disturbance of the heat mechanism being only one, if an essential one, of the processes initiated by the causes of fever. The lectures pass from the consideration of the phenomena of animal heat, of the temperature of the body and its regulation, to the consideration of fever and febrile temperatures, the causes of fever, its stages, the metabolic changes associated with it, the changes in the blood, the disturbances in circulation, respiration and digestion, and the anatomical lesions to which it gives rise. The monograph is dedicated to the memory of Cohnheim, whose masterly volume of lectures form, Professor Löwit says, a milestone in pathological science.

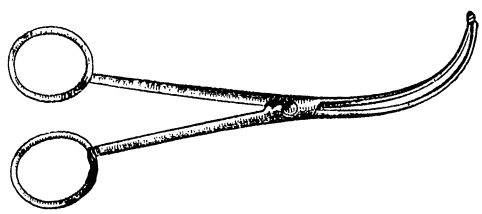
JOURNALS AND REVIEWS.

THE May number of the *Veterinary Journal and Annals of Comparative Pathology* contains an essay which partakes rather of the nature of a class lecture than an essay read before the Edinburgh Veterinary Medical Society, on Laryngismus Paralyticus of the Horse. The reports of societies occupy a very large proportion of this number of the journal. A continuation of the experimental and clinical study of the Aspergillus fumigatus and a few extracts and notes make up a less interesting number than usual. The June number contains a note on Cashaw Poisoning by G. Randolph Abrahms, a form of poisoning induced in horses, mules, and cattle by one of the acacias, the Prosopis juliflora, found in Central America, from Mexico to Guayaquil. Then follow notes, editorial articles, and extracts from foreign journals, with notes and news.

In the *Veterinarian* for May are a number of original papers, amongst which the most interesting is an investigation into the Cause of Louping-ill, by Mr. R. Greig Smith, and Mr. Alexander Meek, the Durham College of Science, Newcastle-on-Tyne. The authors do not attempt to go into the history of the subject, but they approach it from the point of view that louping-ill is the result of some infection with pathogenic bacteria through the agency of the sheep-tick. The experiments as given by the authors are as yet very incomplete. The organisms that are described appear to be scarcely more pathogenic than those met with in utrefying substances; the

Hosted by Google

authors, however, announce that they intend to return to this question in the coming season and to submit the problem to the test of a practical field experiment. Veterinary-Captain R. W. Burke contributes a paper on Kamri or Paraplegia, or partial paralysis, a disease usually accompanied by a partial loss of sensation which may be due, the author considers, to cold, dietetic causes, and to surgical conditions, in the latter case being reflex in character. Veterinary-Captain Burke also contributes a postscript on Surra, in which he maintains, against Dr. Lingard, that there is practically no difference between the surra of horses and cattle and malarial fever in man. Mr. John A. W. Dollar contributes a *résumé* on Roentgen Photography. The Month's Progress contains a number of abstracts of interesting papers, whilst the Proceedings of Societies for this month occupy a space of 134 pages, and some of the discussions are of considerable interest. The June number contains a note on Pseudanthrax in Meat Meals, by Mr. R. Greig Smith, and Mr. J. Arthur Thomson contributes a short paper on the Artificial Insemination of Mammals and one on Rut or Œstrus. The other original articles are one on Swine Fever and its Prevention, by Mr. George Green, and the Prevention and Suppression of Contagious Diseases of Animals, by the late Professor Walley, in which he deals specially with pleuro-pneumonia and anthrax, and then describes the specific eruptive fevers and infective granulomata as diseases disseminated by contagion and infection, taking as his examples of the first cattle plague, variola, foot and mouth disease, and swine fever, and of the second glanders, farcy, and tuberculosis. Professor Walley's conclusions will be of interest from the point of view of those who are engaged in dealing with cattle. A number of Clinical Cases and the Month's Progress, including a good abstract of Dr. Calmette's paper on Snake Poison and Immunity, which appeared in a recent number of the *Annales de l'Institut Pasteur*, are recorded. A complete list of the questions set at the May examination for the diploma of the R.C.V.S. is given; also an account of the meetings of the various veterinary societies.



The Ophthalmic Record. Vol. VI. Edited by CASEY A. WOOD, M.D., of Chicago, and many Leading Ophthalmologists of Nashville, Philadelphia, New York, Milwaukee, San Francisco, Omaha, and other American cities. Clark-street, Chicago: L. D. Pierce. Price, annual subscription, 14*s*. 1897.—We have received several numbers of this journal for the present year. Each number contains original articles, reports of the meetings of societies, reviews, editorial comments, and correspondence. Amongst the more important original articles may be mentioned one by Dr. Edward Jackson on the Location of Opacities near the Posterior Pole of the Lens by means of the Corneal Reflex, in which advantage is taken of the relative rapidity of movement of the opacity across the pupil as compared with that of the corneal reflex, which of course represents one of the radii of the corneal curvature. Another is written by Dr. Louis Lautenbach, of Philadelphia, discussing the influence of nasal disease in modifying the quantity and axis of corneal astigmatism. He thinks this is to be explained by the intimate relation existing between the blood-vessels of the nasal cavities and those of the eye and its appendages, especially their anastomoses, the direct mucous connexion of these organs through the ductus nasalis, and their intimate nervous relations. Another article by Dr. Francis Valk, of New York, deals with the curvature of the cornea in reference to the refractive condition of the dioptric apparatus in the two principal meridians, and Dr. Robert Sattler, of Cincinnati, contributes a good paper, with illustrations, on Sarcoma of the Orbit. In addition to these and other original articles there is a well-executed translation of Dr. Th. Gelpke's article entitled "Study of an Epidemic of Acute Purulent Ophthalmia and of its Cause, the Bacillus Septatus." The journal is well got up and reflects credit on the editors and publishers.

Annals of Ophthalmology. Edited by Dr. CASEY A. WOOD, Dr. CHARLES MAY, Dr. WENDELL REBER, Dr. H. V. WÜRDEMANN, and Dr. ALBERT HALE. Vol. VI., No. 1. January, 1897. St. Louis, Mo: Parker. Price, $1.25=5*s*.—This part contains a considerable number of original articles and presents a good feature in giving abstracts of current ophthalmological literature in American, English, Spanish, German, French, and Italian journals, as well as reports of societies. Amongst the more interesting articles is one by Dr. George M. Gould, of Philadelphia, recommending the use of test-cards with black background and white letters. Dr. F. C. Hotz, of Chicago, has adopted skin-grafting in cases of pterygium when the wound is large with good results in four cases. Dr. Alex. W. Stirling, of Atlanta, Georgia, continues an essay on Glaucoma, chiefly dealing with the character of the cupping of the disc observed in this disease and the consideration of the various theories that have been advanced in regard to its etiology. Dr. Alexander Duane, of New York, supplies a reprint of his prize essay on a New Classification of the Motor Anomalies of the Eye based on Physiological Principles. Lastly, Dr. F. W. Marlow, of Syracuse, gives Clinical Reports of Central Lesions with Eye Symptoms, which are interesting.

New Inventions.

IMPROVED TRACHEA FORCEPS.

THE accompanying illustration represents a pair of curved trachea forceps designed by M. D. Harmer. They will be found to be of much use in removing such material as membrane from a trachea without getting into the operator's light. They will also be useful in removing foreign bodies

from the ears, nose, and throat, and also may be used as sinus forceps in those cases where the ordinary straight forceps are found to fail. Messrs. W. H. Bailey and Son, of Oxford-street, W., are the makers.

A. M. C. GEDDES, M.B, C.M. Edin.
Nurses' Home, Howard's-road, Plaistow, E.

IMPROVED CLIP FOR PERFORMING CIRCUMCISION.

FOR performing the operation of circumcision in Bombay the Mussulman operators use a piece of split bamboo and a sharp razor; the prepuce being pulled through the slit, it is rapidly cut off with the razor, and the results are very good. Messrs. Matthews Brothers (10, New Oxford-street, W.), have made for me a somewhat similar clip or shield, which, being of metal and easily adjusted, is, I find, superior to the above-mentioned simple contrivance, and it is easily cleaned. It is placed in front of the glans penis in a slightly sloping direction, by which too much loss of skin from the under part of the penis is prevented.

THE LANCET.

LONDON: SATURDAY, JUNE 26, 1897.

THOSE of us who were fortunate enough to witness the memorable ceremony of Tuesday last—and it is believed that upwards of one million and a half of persons enjoyed the privilege—saw a sight of unparalleled importance as well as of splendour that it will be hard in the future to outdo. The appearance of the great procession, its length, its order, its wonderful wealth of colour, the historic character of its constituency, its precision of march, and the stirring melody of its accompaniment, have all received due descriptive justice from the great journals of the day, so that to attempt to add to the fulness of phraseology and the completeness of description with which the pageant of the Diamond Jubilee has already been vividly brought before the notice of the world would be as unnecessary as, in our belief, it would be impossible. But while we know that those of our readers who were not actual spectators have since become so familiar with the story that they, as much as the more fortunate section of the community who saw and heard, do not require from us any details of the procession, we think it well to draw just one simple lesson from the day's proceedings, because we believe very implicitly that it is almost impossible to overrate the influence that the QUEEN'S magnificent journey through her great capital may have upon the community.

Beyond all doubt the Jubilee procession opened the people's eyes, their mental eyes as well as their physical. To many the convincing proofs of the wealth, of the power, and of the far-reaching influence of our nation must have appealed with all the force of novelty. It was a veritable revelation. They knew their geography perhaps, but certainly they had never heeded its significance. They had read of distant dependencies and of colonial appointments, but all these things were merely words to them. Of that great entity the Empire they had the most shadowy notions. Therefore, when the splendid Indian soldiers were seen in procession with the flower of the British army, when the Canadian and Rhodesian horse mingled with the Artillery from Trinidad and Jamaica, with the Sikhs from Malay, the Dyaks from Borneo, the Hong-Kong Chinese Police, and the Haussas from the Gold Coast, an object lesson of the most clear significance was at once supplied where it was most wanted. No reams of fine writing on the abstract beauties of unity and the strength thereof, no amount of argument upon the practical advantage of free trade between mother and daughter, no splendid stories of pioneering achievements, no architectural palaces for the collecting and labelling of produce or the housing of archives, and not even the magical swing and impassioned patriotism of Mr. RUDYARD KIPLING'S verse have separately or together furnished such a justification of the necessity of Imperial Federation as was furnished by the Jubilee procession. A justifiable, reasonable pride fills the breast of every man to-day beneath Queen VICTORIA'S sway at the thought that he belongs to so great and so successful a Crown and serves so great and so good a Mistress. And the wide prevalence of such a feeling is true Imperial Federation, a feeling which has recently been glowing with unusual fervour, but which is now flaming. Upon this feeling those capable of reading the times rely not only to produce results that will be pleasing to our patriotism, but results that will be for the lasting good of the world at large.

When all round either hemisphere the British nation joins hands and, from Premier in Downing-street to policeman in Hong-Kong, from Commander-in-Chief in Pall-mall to Haussa on the Gold Coast, works on a noble and liberal scheme for order, justice, and goodness, then will the real sweets of Imperial Federation be tasted; and he would be a bold man who could set any exact limit to the stride that was taken last Tuesday afternoon towards so noble a consummation.

THE President of the General Medical Council and certain of his colleagues are expecting shortly to have an interview with the President of the Local Government Board on the subject of the acceptance of loose information of the cause of death supplied by unqualified practitioners of all sorts. An inquest is reported in the *Cornish Telegraph* which illustrates in a very striking manner the evils of unqualified practice, the audacity of unqualified practitioners, and the appreciation by jurymen of a registrar who has the good sense to decline a certificate of death from such persons. The coroner was Mr. E. L. CARLYON. The subject of the inquest was the death of Mrs. MARY MARTIN, and the unqualified practitioner who took upon himself the responsibility of attending her and certifying the cause of her death was Mr. SAMPSON TAYLOR ROWE, of Redruth, chemist and surgeon dentist, who had no medical degree, but appended the letters Ph.D. to his name, and explained that the title was got from America, and that "it was a scientific degree." The case is further interesting at this moment as showing how effective little pretences are in the case of the less intelligent classes of the community to convey the impression of full qualification and that over a very lengthened period of years.

We may state the facts elicited a little more fully. MARY MARTIN, aged seventy-two years, a delicate woman, was taken ill on a Tuesday, and died on the following day. She was attended in the meantime by Mr. ROWE, who gave the following certificate:—

"Redruth, June 2, 1897. This is to certify that Mary Martin, aged 72 last birthday, died on the 2nd instant from paralysis of the brain (third attack); duration of disease six months.—S. T. ROWE, Ph.D. and C., Registered Surgeon-Dentist and Chemist."

The sister of the deceased said she was always under the impression that Mr. ROWE was a medical man, and had complete faith in him, he having supplied medicine to her for fifty years. When we consider how well satisfied Mr. ROWE was with himself, and what good use he made of certain capital letters of the alphabet after his name, we may cease to wonder that he imposed on the unlearned. Let us analyse Mr. ROWE'S credentials and sit at his

Hosted by Google

feet to learn how a man with no medical qualification can practise medicine and certify deaths for half a century and how, when belatedly brought to book, he shows himself equal to the occasion and full of resource. His reply to one of the many pertinent questions of the coroner is interesting: "*Coroner:* I think you wrote that certificate to deceive. *Mr. Rowe:* I did not. I have been accustomed for fifty years to give the cause of death as an ordinary individual with my name affixed, and it was never questioned until recently. In consequence of its being questioned I have arranged to get a properly qualified man as my assistant." Is it possible that in Cornwall there is any member of the profession so unacquainted with the rules and the judgments of the General Medical Council as to think that he can become assistant to Mr. SAMPSON TAYLOR ROWE and retain his place on the Medical Register? We fear such a thing is not impossible. Only at the last meeting of the General Medical Council a London practitioner was on his defence before the Council for covering an unqualified assistant, and he declared that he had never seen the advertisements of the Council's views and that he was not aware that there was anything illegal in what he was doing. The practitioner was eighty years of age and did not seem to realise the new conditions of medical practice. But we should advise any gentleman with whom Mr. ROWE may have arranged an assistantship not to rely on any similar leniency on the part of the Council. All men are not eighty years old, and even the patience of the General Medical Council has its limits. But we are concerned to-day not with Mr. ROWE'S future qualified assistant, but with the devices with which he has continued for fifty years to convey to the public the impression that he was a medical man. He is indignant at the idea of the coroner that he meant to deceive. He says he did not give a medical certificate. He cannot deny that he wrote a certificate in such a form and with such a parade of letters as were meant to resemble a medical certificate. No thanks to him that it did not run and that the bogus character of his credentials and his claim to pose as a medical man have now been fully exposed. The phalanx of letters was so arranged as to suggest validity and respectability in the certificate—"Ph.D. and C., registered surgeon dentist and chemist." Nor can we congratulate Mr. ROWE on the light which he has thrown on the letters Ph.D. and the way he came by such a title. When asked if his degree was granted after examination he replied to the questioner, "That is my business, not yours." He afterwards admitted that it was from the University of Philadelphia, which has an unpleasant reputation for bogus degrees. The coroner made some important observations on the disadvantages to the public of such irregular practitioners. They may attend infectious cases, but are not compelled to notify, and do not incur the penalty for non-notification. The law allowed, he pointed out, deaths to be registered on such information as in this case, though they were registered as not certified. It was impossible to say whether the treatment was right. The jury found death to be due to natural causes and desired the coroner to severely censure Mr. ROWE. It will be interesting to see the further development of Mr. ROWE'S practice in connexion with the "properly qualified man he has engaged to get." But, apart from his arrangements, it is high time that the whole system of unqualified practice in all its forms was more systematically studied by the General Medical Council. We are aware that it has no power over such gentlemen as Mr. ROWE, whatever it may have over his "properly qualified" assistant, but it has power and it is its duty to represent to Government the unsatisfactory state of the law, and in the interest of the public to demand an amendment.

AT the approaching election of members of the Council of the Royal College of Surgeons of England, the five vacancies which at present exist will be filled, and it behoves all Fellows of the College to consider carefully in what manner they will exercise their voting powers on July 1st. The duties of the Council are many and diverse; to their care is entrusted the maintenance of the valuable library, and the unrivalled museum of comparative anatomy and pathology, the foundations of which we owe to the skill and enthusiasm of JOHN HUNTER; they have to safeguard the dignity of the profession by seeing that none of the Fellows or Members of the College transgress the wholesome rules of medical etiquette; all these are onerous duties, but by far the most important of the many functions of the Council is the very large and important influence the College has on medical education. On the curriculum which they lay down and on the standard of the examinations they conduct depend the surgical training and knowledge of a very large proportion of the medical profession of this country. In exercising, therefore, his right of voting for members of the Council it is the duty of every Fellow to bear in mind that by his individual vote he may make or mar the surgical training of many future medical practitioners. It is not enough that a member of the Council should be a distinguished surgeon; he should be practically acquainted with the medical education of the present day or at least be familiar with its aims and requirements. For this to be possible it is not absolutely essential that he should be connected with a medical school, though it is obvious that the candidates with the desired qualifications are likely to belong to medical schools. Other things being equal it is on the whole desirable that members of the Council should not at the same time be examiners at the College, but a practical difficulty arises: the Council chooses the best men for the posts of examiners, and there can be small reason for surprise that it often happens that the same surgeons are the most suitable candidates for seats on the Council.

At the present election there are five vacancies to be filled; three of these have been created by the retirement "in rotation" of Mr. CHRISTOPHER HEATH, Mr. HOWSE, and Dr. WARD COUSINS. Mr. HEATH does not seek re-election; he has already served two terms, and has been elected president twice. For the five vacant places there are no less than eleven candidates. Three of the candidates are provincial Fellows, namely, Mr. BENNETT MAY, Mr. GEORGE JACKSON, and Dr. WARD COUSINS; and there seems to be a general desire, at least among Fellows residing in th country, that provincial Fellows should be well represented on the Council. We may express the hope that Mr. BENNETT MAY may

Hosted by Google

be elected. The eight remaining candidates are Mr. HOWSE, Sir WILLIAM DALBY, Mr. CLEMENT LUCAS, Mr. EDMUND OWEN, Mr. ANDREW CLARK, Mr. RICKMAN GODLEE, Mr. J. H. MORGAN, and Mr. WATSON CHEYNE. Mr. HOWSE has served one term and has done his work so well that it would be distinctly a loss to the College if he were not re-elected. Mr. CLEMENT LUCAS is a colleague of Mr. HOWSE at Guy's Hospital, and his election would increase to four the number of members of the Council derived from that school. This may not be an ideal arrangement, but it cannot be disputed that Mr. LUCAS would decidedly prove a gain to the Council. Mr. RICKMAN GODLEE is a well-known surgeon attached to University College Hospital, and as one of the representatives from that hospital—namely, Mr. HEATH—is retiring from the Council, Mr. GODLEE might very fitly replace him. Mr. EDMUND OWEN is the senior surgeon to St. Mary's Hospital, which is at present unrepresented on the Council; we are inclined to think that Mr. OWEN'S sympathies are rather too conservative for him to assist adequately in the necessary progress of the College; but we do not doubt that, if elected, he would do his best to maintain the high character of the examinations. Mr. J. H. MORGAN has for a long time been an earnest advocate of necessary reforms in the College. He was one of the founders of the Association of Fellows, and was one of its honorary secretaries in the early and more fruitful years of its existence. He is well acquainted with the problems of medical education from his position at Charing-cross Hospital, and would, we feel sure, be a decided acquisition to the Council. Mr. WATSON CHEYNE is well known to a large section of the medical public, and at the present time King's College Hospital has no representative. Mr. ANDREW CLARK is hardly so suitable a candidate as several of the others, though he has had much to do with medical education at the Middlesex Hospital. Sir WILLIAM DALBY has done much good work, but perhaps he is not now quite in touch with our present day questions of education; and we may say in conclusion that in our opinion the candidates who would most satisfactorily assist in the work of the Council—surgical, educational, and ethical—are Mr. HOWSE, Mr. LUCAS, Mr. GODLEE, Mr. BENNETT MAY, and Mr. MORGAN.

Annotations.

"Ne quid nimis."

THE DIAMOND JUBILEE HONOURS.

THE medical profession has no reason to consider that it has been left in the cold in the distribution of Diamond Jubilee Honours. It is true that the greater part of the honours bestowed upon medicine were foregone conclusions, that is, they are either promotions in the orders reserved for official service or recognitions of high official place, but this is the character of the whole list, and has doubtless been deliberately maintained as the only possible course to be pursued on an occasion where so many diverse claims might have been considered from a sentimental point of view. Dr. Wilks, the President of the Royal College of Physicians of London, receives the baronetcy which his eminent services to science and to the practical philanthropy of Guy's Hospital so well merit. Sir William MacCormac, the President of the Royal College of Surgeons of England, can also doubly justify his baronetcy, being a sound surgeon as well as a good organiser and a dignified official. Mr. Thomas Smith's baronetcy will be exceedingly popular in the profession, where his operative skill is as widely recognised as are his amiable qualities. No harder working or more brilliant exponent of modern medicine, of medicine as an exact science rather than as an interesting art, could have been selected for knighthood than Dr. W. R. Gowers. If only all those members of the profession who have delighted in his treatises should recognise the honour given to the author, Sir William Gowers will receive as many congratulations as anyone in the list. There is a fitness about the bestowal of a knighthood upon Dr. Felix Semon, as he is a skilful exponent of a branch of medicine which has been born and has reached its present sturdy size entirely during the Victorian era. We are glad to see in the lists of new knights the names also of Dr. George F. Duffey, the President of the Royal College of Physicians of Ireland, and Mr. William Thomson, the head of the corresponding surgical corporation. Among the promotions in, or selections for, the Order of the Bath, we notice several well-known names—notably, Dr. Richard Thorne Thorne, who becomes K.C.B. (Civil); Inspector-Generals of Hospitals H. F. Norbury, J. J. L. Donnet, and H Macdonnel, and Surgeon-General C. A. Gordon: K.C.B. (Military); Dr. T. Grimshaw, Registrar-General of Ireland; Dr. David Nicolson, one of the Lord Chancellor's Visitors in Lunacy; Surgeon-Major-General J. Jameson, Director-General of the Army Medical Department, and Mr. Hugh Adcock, Consulting Physician to H.I.M. the Shah of Persia: C.B. (Civil); and Surgeon-Major-General C. Sibthorpe and Brigade-Surgeon-Lieutenant-Colonel G. W. McNalty: C.B. (Military). Surgeon-Major-Generals W. R. Hooper, President of the Medical Board, India Office, and J. Cleghorn, Director-General of the Indian Medical Service, receive the honour of C.S.I.; and Messrs. W. M. Haffkine, A. F. R. Hœrnle, and J. Husband, that of C.I.E. Dr. J. Mackie, the President of the Egyptian Quarantine Board, and Dr. C. Gage Brown, the Medical Adviser to the Colonial Office, are promoted to K.C.M.G., and Dr. S. W. Bushell receives the C.M.G. Deputy-Inspector-General of Hospitals H. C. Woods receives the Royal Victorian Order (4th Class). So much for the strictly medical honours, but we notice among the names those of many men distinguished in the scientific and philanthropic world with whose labours the medical man has necessarily much sympathy and sometimes a close connexion. We heartily congratulate, for example, Lord Rowton, who becomes a K.C.V.O.; Sir J. Blundell Maple, who receives a baronetcy; and Mr. H. C. Burdett, now Sir Henry Burdett, K.C.B., on the recognition which their powers of practical organisation have received. We are also glad to see among the new knights the names of Professor Crookes, the eminent chemist, Mr. Binnie, and Mr. Wolfe Barry, the engineers, Dr. Huggins, Mr. Christie, and Dr. Norman Lockyer, the astronomers; and Dr. Edward Frankland, whose researches into the method of securing a pure water-supply have certainly deserved a reward from the State.

MEDICAL FEES AT INQUESTS.

MR. JOSEPH JOHN CLARKE, of Walthamstow, who ordered an injured woman into hospital and, when she died, gave evidence at the inquest in response to a summons, sued the coroner, Mr. Charles Edgar Lewis, at Brentwood County-court, to obtain a guinea for his remuneration. The case being of some importance plaintiff was represented by a barrister, Mr. W. Ellis Hill, instructed by Messrs. Le Brasseur and Oakley, the solicitors to the London

Hosted by Google

and Counties Medical Protection Society, Limited, and the South Essex coroner, who was defendant, was represented by the South-West London coroner, Mr. A. Braxton Hicks, who is also a barrister. Mr. Hill said that in the Coroners Act there is a provision that where an inquest was held on the body of a person who had died in a hospital or infirmary used for the reception of patients the medical officer whose duty it might have been to attend to such deceased person as medical officer of such institution should not be entitled to recover any fee or remuneration. The plaintiff, counsel added, was not the medical officer of the institution. Mr. Braxton Hicks resisted the claim because, he said, coroners, if they paid fees to these medical men, were surcharged by the auditors. His Honour held that the plaintiff was not the medical man whose duty it was to attend the deceased person as medical officer of the hospital and was therefore entitled to his fee as a witness. Judgment was given for plaintiff, with costs on the higher scale. Mr. Braxton Hicks said the case would be taken to the High Court, and leave to appeal was given.

EXPERIMENTS ON LIVING ANIMALS: THE RETURN TO THE HOUSE OF COMMONS.

IN a Return made by the Inspectors under Act 39 and 40 Vict., c. 77, showing the number of experiments performed on living animals during the year 1896 under licences granted under the Act, we have a fuller account than usual of the working of the Act and a more detailed statement of the nature of the experiments performed. The total number of licences held in England and Scotland during the year 1896 was 236, under 70 of which no experiments were performed. These licences and certificates have in every case been granted and allowed only upon the recommendation of persons of high scientific standing, and care has been taken that the licensees should be by their training and education fitted to undertake experimental work and to profit by it, and that all experimental work should be conducted in suitable places. In his report Dr. Poore has classified the experiments, separating out those that are of the nature of inoculations and hypodermic injections from the rest, and placing them in a class by themselves. He points out that the process of inoculation is inadequately provided for in the Act of Parliament, and states that "it would be cruel rather than otherwise to anæsthetise an animal before subjecting it to the trivial operation of a prick with a needle, and yet the wording of the Act is such that the administration of anæsthetics can in no case be dispensed with except by a certificate (A) stating that 'insensibility cannot be produced without necessarily frustrating the objects' of such experiments. Notwithstanding that the wording of Certificate A is not wholly applicable to the circumstances, it is nevertheless allowed for inoculations." He then goes on to point out that the rapidly increasing knowledge of the various diseases caused by micro-organisms has necessitated the study of the life-history of these organisms by such inoculations, and further shows that inoculation is largely used for the diagnosis of disease in man and animals; that the preparation of mallein and tuberculin tests and the preparation and testing of antitoxins necessitate hypodermic injections in order that the strength and purity of these substances may be determined. The experiments, not merely inoculations and hypodermic injections, are 1516 in number; of these 969 were performed under the licence alone and 184 under certificate C; in both cases the animals suffered no pain, complete anæsthesia being maintained during the whole of each operation and the animal killed before it was allowed to come from under the influence of the anæsthetic. Under Certificate B 188 experiments were performed, and under B along with Certificate EE 175. Here the animals are under the influence of anæsthetics during the whole of the operation, which, as well as the subsequent treatment, is carried out under antiseptic precautions so that no pain results during the process of healing. Of the painless and hypodermic injections 5984 were made, most of these (5217) being carried out under Certificate A on small rodents, 67 under Certificate A+E, 13 under Certificate A+F, and 687 under Certificate B, those under Certificate B being in almost every case rabbits inoculated with rabic material, anæsthetics being used during the operation. It is interesting to notice that one of the only two cases in which the letter of the Act was doubtfully complied with was due to excessive care on the part of the licensee to avoid giving pain, as he administered an anæsthetic for four subcutaneous inoculations. The second case was that of a licensee who holds no certificate who inoculated a series of four mice with the ringworm fungus. As the Inspector points out, "it would be cruel rather than otherwise to administer an anæsthetic for such a proceeding. No experiment under the licence alone, however, can be performed without an anæsthetic, and the licensee held no certificate enabling him to dispense with anæsthetics. It might possibly be contended that such a proceeding is not "an experiment calculated to give pain" within the meaning of the Act. This, however, is a question which has to be decided by the licensee and those who sign his application for a licence. In the report signed by the Inspector for Ireland we learn that 7 licences were in existence, 3 of which expired during the year, and 3 were granted to gentlemen who had been previously licensed, and 2 to new experimenters. "Twenty-nine experiments were performed by one licensee, and 31, 15, 15, and 7 by the holders of certificates, the animals used being birds, monkeys, rabbits, mice, and rats. The experiments were all painless, except so far as a needle-puncture in some cases; 15 were directed to the investigation of the oxygen tension of the arterial blood, 29 to an examination of the nervous mechanism which governs respiration, 15 to trace the paths of the conduction of nervous influence, and 38 to the investigation of canine rabies for State purposes." He goes on to say that "all the experiments were, in my opinion, useful and calculated to throw light on vital phenomena, and on the relief of disease, and so to assist in the treatment of suffering." These analytical reports should go far to show how carefully regulated are experiments under the Act, and anyone who will read this Return impartially will be struck by the high sense of responsibility that characterises the observations of the Inspectors, who, whilst unwilling to hamper experimenters in any way, take the most careful precautions to carry out the requirements of the Act not only to the letter but in the spirit of those who framed it—to prevent cruelty of all kinds and unnecessary pain in every instance.

FARM SANITATION AND MILK SUPPLY.

MR. G. H. DE'ATH, the medical officer of health of the Buckingham Urban Sanitary Authority, has done good service in publishing a *brochure* upon the very important subject of the sanitation of the farm with reference to milk supply. He points out how scrupulous is the observation of the rules of thorough cleanliness in the dairy farms of Holland and Denmark, and urges the necessity for greater circumspection in the management of cows, and especially in regard to the purity of their food and drink. It is certainly singular that so small attention is often paid to such matters, which must influence the health of the animals who yield one of the staple foods of man. But of equal importance is the care of the farmyard, the cowshed, and the utensils used in the collection and storage of the milk, and Mr. De'Ath gives many useful and practical hints in these and other directions. The pamphlet closes with a vigorous

Hosted by Google

protest against the prevalent practices of the milk trade, which was read at the Bucks Sanitary Conference in October, 1894, under the title of the "Sanitary Protection of the Milk Traffic." We trust that the lessons which Mr. De'Ath so plainly and forcibly teaches will be taken to heart by those concerned, and that farmer and dairyman alike will recognise that it is to their own interests that the conditions under which their milk is produced and sold shall be such as to guarantee the purity of the article. To attain this is not merely a matter of the avoidance of adulteration, but one of he application of the common-sense principles of health to the care of cattle, and the enforcement of the most rigid rules of cleanliness.

THE NEW YORK CITY DISPENSARY BILL.

THE Bill introduced into the State legislature with the object of remedying the abuses of the dispensaries in New York City, after being approved by the legislative body at Albany, has been rendered of no effect by Governor Black refusing to affix his signature thereto. This unexpected action on the part of the Governor has caused much surprise. The majority of the medical profession in New York City are deeply disappointed at the failure of the Bill to become law, as it was generally considered well calculated to remedy many of the existing abuses and in other ways to put affairs connected with medical charities on a better footing. Nevertheless, matters are not to be allowed to continue in their present unsatisfactory condition. The local medical men are thoroughly aroused and are determined that a change shall be made in the conduct of the dispensary system. The fact is clearly recognised that things have already been allowed to drift too long, and are rapidly going from bad to worse. It is realised that unless a strong and determined effort is promptly made to effectually stamp out most of these abuses it will be too late to save the whole charity system from shipwreck. The *City Press* (New York) has taken up the matter in the energetic manner usual to the American newspapers when they inaugurate a crusade directed against any social evil. The *New York Herald* has been especially active, and published recently an outspoken leading article indicting the management of the dispensary charities. A part of the article ran as follows: "From what we can learn both parties in the controversy—the medical staff and the boards of management—are equally to blame. The doctors in their eagerness for clinical material are inclined to treat all interesting cases indiscriminately, whether able to pay or not, and the managers are anxious on general business principles to make a good showing for the institutions under their charge. No one doubts the fact that the majority of the patients treated in the dispensaries are able to pay the physician a legitimate fee and are consequently undeserving applicants. It is also true that the dispensaries are too numerous—are out of all proportion to the actual needs of the really poor patients, and are slowly but surely fostering a most dangerous form of pauperism. London is suffering from the latter condition, and New York is falling in the line of its bad example." From a perusal of the foregoing the fact will be grasped that there is much similarity between the abuses of the medical charities of New York City and London. In both places it has been proved up to the hilt that abuses on a very large scale do exist. In both places the management and medical men are to blame, and in both places the dispensaries and special hospitals are too numerous. In the *Forum* for June is an article by Dr. Geo. F. Shrady, entitled "The Dispensary, a Propagator of Pauperism." The subject is ably treated from every point of view, and some of the facts narrated will come as a revelation to many citizens of New York as well as to Englishmen who interest themselves in social affairs. Dr. Shrady says: "It may be broadly stated, as the result of exhaustive statistical study, that fully 50 per cent. of the patients who apply for free medical aid are totally undeserving of that charity. The main fault lies with the managers. In New York alone there are 116 dispensaries, each one of which is vying with the other in propagating the worst form of pauperism. It would appear that charity is monopolised in the same way as any other marketable commodity that is ruled by money. The millionaire philanthropists stand in the same relation to the medical profession as did the camel to the Arab when his beast asked the privilege of poking his nose into his master's tent; when the camel finally occupied it there was no room for the owner, and he was forced to vacate accordingly." Several striking instances are given in this article illustrating the deceptions to which rich persons will stoop to cheat charity and the medical man. We quote the most bare-faced case as told by a dispensary physician. "A wretchedly-clad woman presented herself to me at the dispensary and asked for treatment. She gave a name which I afterwards found was assumed. She was badly in need of attention, and said that she could not pay. I believed her and agreed to treat her. It was an interesting case, and she consented to appear before the class of fifty or sixty practitioners. One day after she had been before the class several times and treated I was driving with my wife in Central Park; we were passed by a magnificent team and carriage, spanking horses, nobby coachman and footman, and glittering harness. In the carriage was a lady whose features were familiar, but I could not remember where I had seen her. That same day my charity patient presented herself attired as usual in the poorest clothes. I recognised her as the lady of the fine turn out. I said nothing, as I thought I would investigate. A few days later I saw the same carriage in front of a fashionable shop, and got a good view of my patient as she alighted. When she next came to the dispensary I asked her for her real name. She gave me her assumed dispensary one. I told her she was deceiving me, and she finally disclosed her identity. She was the wife of a man known all over the city as a millionaire. I sent a bill to her husband and it was paid without a word." The suggestion is made that the control of dispensaries should be vested in a State Board of Charity, which should be granted ample powers to regulate their management, and without doubt at the next session of the Legislature another Bill will be introduced.

THE LATE DR. R. M. GOVER AND MILITARY PRISONS.

A WELL-INFORMED correspondent writes to us as follows:—"Since the publication of your obituary notice of the late Dr. R. M. Gover, H.M. Inspector of Prisons, my attention has been called to the late officer's connexion with the institution at Millbank, with its department for military prisoners. If anyone will take the trouble to refer to the published reports of the House of Commons for many years prior to 1878 it will be found that questions were being constantly addressed to the Minister for War regarding the impaired state of health in which soldiers were discharged from prisons after having undergone their terms of imprisonment. In 1877 the then Secretary for War (Mr. Gathorne Hardy) determined to have the subject of these frequent complaints investigated, and a War Office Committee was appointed for that purpose. The army medical member of the committee, Surgeon-Major J. A. Marston, after long inquiry at Millbank and elsewhere, and after having gone fully into the subject, proposed a scale of diet for military prisoners which was finally adopted. It is a curious fact that the proposed scale before adoption was submitted to a medical expert and another authority, but did not meet with the approval of either, one

Hosted by Google

disapproving on the ground that the diet was worse than that for which it was proposed to be substituted, and the other because it was altogether too good. The result of some months' trial of the new dietary at Millbank showed, however, that it fully answered its purpose, that it did not entail additional expense, and that its adoption had the effect of preventing loss of weight among the military prisoners. Moreover, the late Dr. Gover expressed his great satisfaction with the results of the trial of the dietary in question, and added that the amount of petty crime among the military prisoners had been reduced since its adoption. It is believed that from that time to the present there have been no complaints in Parliament on the subject."

MALARIA IN CONNEXION WITH METEOROLOGICAL CONDITIONS AT SIERRA LEONE.

SURGEON-MAJOR E. M. WILSON, C.M.G., lately senior medical officer at Sierra Leone, has published some brief notes and statistical tables illustrative of the effect of meteorological conditions on the malarial fevers endemic at that station. The inferences which the author draws from his observations appear to be well worthy of notice. Briefly expressed they are as follows:—Each battalion of the West India Regiment suffers exceptionally from fever during the first year of its service on the coast, the number of admissions and deaths falling in a marked degree in the second and still more in the third year. The white troops suffer much more than the black. The largest number of cases occur in the middle of the rainy season, in the period of the greatest rainfall and of the highest relative humidity and lowest temperature in the shade—i.e., July and August. The smallest number of cases occur in the period of least rainfall, least relative humidity, and greatest heat. The most important factor in influencing the disease seems to be the relative humidity of the atmosphere. The black troops are more affected by changes in the meteorological conditions than the white. The case mortality, or percentage of deaths to attacks, is small at all periods. The tables are well worth consulting by those interested in the subject, affording, as they do, very useful indications as to the prevalence of climatic fever sickness at Sierra Leone; and the author embodies some useful information in his notes commenting on this, and in his remarks regarding malaria generally and the proper dietary to be issued to troops serving in this climate.

THE POLLUTION OF THE AVON BY THE BRISTOL SEWAGE.

THE influence of a sewage-polluted river upon the health and well-being of the inhabitants on its banks is a difficult question upon which there is some divergence of opinion and not a little conflicting evidence. It is always a difficult, if not an impossible, matter to detect in the death-returns of the neighbourhood the evidence of mischief, but although this is so it would be absurd to infer that no harm results; and there is, indeed, often an abundance of evidence too weighty and well founded to be lightly dismissed, that during periods of drought and heat much nuisance is caused by the effluvium from polluted streams; and, further, that vague symptoms of illness together with a lowered vitality, and perhaps septic complications of diseases are traceable to this cause. If, too, no such evidence as this were forthcoming, it would far from justify the continuance of a grave nuisance, which interferes with at least the happiness of many persons immediately concerned. The sewage of Bristol is discharged untreated directly into the river Avon as it flows through the city, and although it is stated that during ordinary times the scour of the tide is such that no nuisance arises, there would seem to be, from the reports which have reached us, no escape from the conclusion that during hot and dry summers a very considerable nuisance and much discomfort is occasioned by the sewage in question. It appears, in fact, that last year the nuisance was so great that its consideration was referred to a special subcommittee, but it does not seem that up to the present time the members have seen their way to decide upon a definite scheme. Dr. Davies, the experienced medical officer of health of Bristol, has remarked that "the very definite, persistent, and increasing complaints of nuisance from this cause must be allowed considerable weight," and he seems to think that it would be the best course to carry the intercepted sewage at once to the Bristol Channel, unless it can be properly dealt with at some intermediate point before its discharge into the river. Whatever course be adopted after due consideration will, it is to be hoped, be proceeded with without undue delay, inasmuch as the evidence seems to point to the fact that the nuisance is increasing side by side with the growth of the town and the consequent augmentation of the sewage. Bristol is well able to afford the cost of an adequate scheme, and we may rest assured that Dr. Davies will advise the council upon the best course to be adopted. We do not contemplate that in the meantime Clifton and Bedminster will become "depopulated," but the nuisance can scarcely be advantageous to the reputation of a health resort. To those who are taking up the question in a scientific aspect we would recommend the perusal of the First Report of the Royal Commission upon Metropolitan Sewage Discharge, in which will be found some interesting evidence on the effects of river pollution and on the movements of sewage in tidal waters.

FLAT-FOOT: ITS CAUSES AND TREATMENT.

IN our issue of July 18th, 1896, we directed attention to certain recent investigations into the pathology and treatment of flat-foot. From these it was evident that the deformity in question is due to pressure acting upon the inner side of the foot through the medio-tarsal joint—i.e., the joint between the os calcis and astragalus on the one hand and the cuboid and scaphoid on the other. Abduction of the foot followed from the same cause, and its correction was an essential feature in treatment. A similar view is explained with much clearness and also much ingenious detail by Dr. Newton Shaffer in the *New York Medical Journal* of May 29th, 1897. His paper is further interesting as showing the part played by the tough plantar fascia in resisting the downward pressure, and especially the influence of contraction of the post-tibial muscles as tending to overcome this resistance by directing pressure upon the medio-tarsal joint. It may be mentioned that he includes under this term the tarsal articulations anterior to that above described. He thus explains his position: The plantar fascia, which never ruptures, can be stretched. When with a shortened gastrocnemius there coexists a weak and flabby plantar arch, the heel being unable to descend, the arch itself yields at its weakest point, which is the medio-tarsal joint. The scaphoid is pressed down, the inner side of the foot elongated and abducted, and flat-foot is thus produced as a natural sequel to a condition which at first sight appears to negative its production. Dr. Shaffer states that among hundreds of cases treated by him in orthopædic practice he can recall only three or four in which there was not an abnormal tension of the tendo Achillis. He suggests three lines of treatment as being equally logical and more or less practicable: (1) To divide the tendo Achillis and, if needful, the peronei and tibialis anticus which act with it, so as to "crowd the os calcis forward" and relax the plantar tissues, and then to apply an apparatus to adduct the foot; (2) to stretch these tendons under an anæsthetic,

Hosted by Google

and then apply the apparatus; and (3) by the gradual action of mechanical means to attain the same result. This latter method he has used with success even in some chronic cases. It consists in supporting the weak plantar arch with a metal piece worn inside the shoe, in depressing the forepart of the foot beyond the medio-tarsal joint by means of a screw foot-piece, and in depressing by similar means the heel while supporting the astragalus. Later an ankle support is worn, and is so made as to cause the patient to walk on the outer side of the foot. Dr. Shaffer's paper contains much that is of interest to the practitioner, and is illustrated by carefully constructed diagrams.

THE SANITARY INSPECTOR IN EXCELSIS.

THE astounding length to which sanitary inspectors in Scotland are prepared to go with regard to their own ability to perform the duties of medical men could hardly receive better illustration than is afforded in a letter to the *Glasgow Herald* by Mr. Peter Fyfe, sanitary inspector, Glasgow. He writes as follows regarding a previous letter which had appeared in that journal:—

"Dr. Nasmyth makes another statement which I feel some hesitation in remarking upon, but as it would, if uncontradicted, do injustice to many qualified inspectors in sanitary practice, I must refer to it. He states that 'sanitary inspectors are not qualified to examine cases of disease,' and therefore the right of examination of patients is not conferred upon them, and draws an inference from that that as they are not, in his opinion, qualified to certify danger or injury to health, similarly no such right ought to be conferred on them. Now, sir, I know personally sanitary inspectors who through experience are very much better qualified to examine and certify cases of infectious disease than medical men are who perhaps have seldom had a chance of seeing these cases, and several cases have occurred where sanitary officers have had to contradict and correct the medical certificate which was granted with reference to infectious cases."

Surely this is a case of vaulting ambition over-leaping itself. There is an old proverb about the results of setting a beggar on horseback, which need not be quoted here, but we really think that our readers, whether medical officers or not, can make excellent use of the passage quoted. We repeat what we said in a recent issue, that it is the duty of every medical man, and especially of every medical officer of health, to call the attention of his representative in Parliament to the extraordinary proposals of the Public Health (Scotland) Bill—the essence of the proposals being to give to sanitary inspectors, of whom the law requires no qualification of any kind, statutory power to certify danger or injury to health.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.

LORD PLAYFAIR gave an excellent address at the Diamond Jubilee meeting of the British Institute of Public Health on the 16th instant; and the speeches delivered by Sir James Dick, Director-General of the Navy Medical Department, Surgeon-Major-General Jameson, Director-General of the Army Medical Department, and Dr. Thorne Thorne, medical officer of the Local Government Board, were also distinctly interesting. The various speakers garnered up the rich harvest of facts illustrative of the progressive hygienic changes that have taken place during Her Majesty's reign within their respective spheres of knowledge. There is no need to dwell upon the very different, wiser, and more practical standpoint from which we now regard epidemic disease. In every direction the progress made in public health and preventive medicine has been great and fruitful of results. It has become more and more evident that there is no short cut or royal road to safeguard people against disease, but the right way has been all along apparent if we would only have heeded it. The aim to be attained has been wholesomeness of life and surroundings, clean air and water and food, and a clean soil to live upon. Epidemics of typhus fever, once so common among the poorest and most overcrowded of our urban populations, have been practically abolished, and the health of our navy and army has undergone an immense improvement. The wonder was not that so many, but that so few, of our troops died from disease under the conditions in which they were placed before the Queen ascended the throne. About the year 1820 the troops in the West Indies slept in hammocks touching each other, only 23 inches of lateral space being allowed for each man; and at the same time in England many of the men slept in beds with two tiers like the berth of a ship, and not infrequently each bed held four men. The barrack accommodation and the overcrowding of our troops in barrack-rooms everywhere was deplorable; and it is needless to say that the barrack-room atmosphere was, in hot climates especially, sickening. There are, no doubt, still many bad barracks, but the worst of them is incomparably superior to the best that existed then; and all those which have been erected of late years are very good, and have been constructed with a due regard to all sanitary requirements and the best attainable convenience and comfort for their occupants. The accommodation for married soldiers and their families has been revolutionised. Contagious ophthalmia, so common in our army in pre-Crimean times and for some years subsequently, has been practically abolished by the sanitary and hygienic changes that have been introduced into our barracks and barrack-room life by the increase of cubic and superficial space, improved systems of ventilation and ablutionary arrangements, and, thanks to Listerism and antiseptic methods of treatment, the disease, when it occurs abroad or during a campaign in Egypt, is usually cured before it assumes the acute and distinctive form of purulent ophthalmia. We no longer encounter actual patients, as was common in our army years ago, or soldiers invalided by the disease with watery, bluish-red eyes, contracted brows, and blinking lids and shuffling gait, so indicative of intolerance of light and the chronic lesions of ophthalmia. If all the changes favourable to health that have been wrought in other respects in our army during the sixty years' reign of the Queen are not so obvious, they are none the less real, and those who witnessed the grand and imposing spectacle of Tuesday last can have no misgivings, at any rate, as to the physical health and efficiency of those of Her Majesty's forces who took part in it.

FŒTAL TYPHOID FEVER.

AN interesting paper on the above subject appears in the *Medical News* (New York) of May 15th of this year by Dr. Crozier Griffith of Philadelphia. The writer remarks that the transmissibility of certain infectious diseases from mother to child has long been an admitted possibility, yet without there being much demonstrative proof of the passing of any germ from one to the other. Syphilis can undoubtedly be given by a mother to her offspring, and for years it was just as firmly believed that tuberculosis was constantly transmitted in this way. A certain reaction then took place, and it was claimed that inheritance existed, not of tuberculosis itself, but of susceptibility to contract the disease later. This would appear to represent the true condition in the majority of instances, but there are a number of cases on record in which tubercle bacilli have been discovered in the tissues of infants born of women suffering from tuberculosis; and the same has been found equally true of the calves of tuberculous cows. When we come to a consideration of the acute infectious diseases we find that children may in rare cases inherit the disease directly and be born suffering from it, or may in other rare instances complete the attack while still *in utero*. This has repeatedly happened in the case of variola, the children being born with the marks upon them. As an addition to the above remarks of Dr. Griffith we may

Hosted by Google

say that we examined a case of an infant born at the eighth month, the mother at the time suffering from anthrax. We found numerous bacilli in the maternal portion of the placenta, but not in the fœtal portion. The infant survived its birth a few hours, but there were no indications that it was afflicted with the disease. With regard to typhoid fever the question has been more difficult of solution, since the symptoms are less well marked. Yet cases of apparent typhoid fever in the newly-born have been reported by Charceley, and Hastelius found lesions strongly suggesting the disease in a stillborn child of a mother dying from typhoid fever. Dr. Griffith records his case in which the Widal test was used. A family epidemic of typhoid fever occurred in the practice of Dr. J. O'Malley, of Philadelphia, and the father, mother, and three children, the oldest being five years of age, were brought to the St. Agnes Hospital. On Nov. 18th, 1896, the mother, still ill from fever in the hospital, gave birth at term to a well-developed child. It was concluded that the mother was probably in the third week of the disease when labour took place. The infant seemed to be healthy in every respect except for a slight transitory jaundice. When the child was about seven weeks old a specimen of blood was obtained and submitted to the Widal test. In four minutes the bacilli became much less active and began to collect in groups, and some little time later they became agglutinated. The conclusion drawn from the case is either that the child had had typhoid fever *in utero* and recovered after a short attack, or that the agglutinating principle had passed through the placenta from the mother to the fœtus without the latter having contracted the disease at all. There remains also the hypothesis that the child had imbibed the virus with the mother's milk. Analogy to other infectious diseases, and the fact that fatal typhoid fever does occur, render the first supposition most probable—namely, that the child when born had already had an attack of the fever.

THE HANDEL FESTIVAL.

AMONGST the remarkable developments of the Victorian era must be counted the growing taste of the public for good music. This may be attributed, we think, partly to the earnest efforts of our musical leaders some years ago to cultivate the public taste and to provide or lay the ground for the performance of works of real worth, and partly to the demand which is created by the ever-increasing pace of modern life for a source of true recreation for the mind as well as for the body. The great event held every three years at the Crystal Palace, when, with few exceptions, the choicest of Handel's inspirations are performed, is an important factor towards complying with this healthy and natural demand on the part of the public for this wholesome form of mental recreation. There could have been little disappointment in the mind of the great crowd which assembled on three occasions last week to hear the rendering of Handel's choruses by a choir of 4000 voices. Nor could any dissatisfaction have been expressed in regard to the execution of Handel's delightful melodies by the soloists. The programme of the great Handel week was very much in a line with that followed on previous occasions. For ourselves we confess that some little departure might with advantage have been made. The great composer has supplied a superabundance of material both for vocal and orchestral execution from which to make a selection. But we admit that there must be a considerable difficulty in including every choice excerpt. Handel wrote twelve organ concertos, and, as far as we recollect, the 1st in G major and the 2nd in B flat are played over and over again. Surely the authorities might occasionally give us the 11th in G minor, with its delightful second movement on a ground bass, or the 9th in F major, with the two charming minuets. Perhaps we may hear one of these at the next festival. As medical journalists there is little which calls for remark from us from our own peculiar point of view. We trust, however, that the interest in these festivals will never languish, and we are glad there is no reason for thinking that it ever will, in view of the splendid attendances which were recorded last week. From a point of view of a musical performance we believe, and those competent to judge have said, that the recent eleventh triennial event was an unqualified success. The first performance on Monday must have appealed to those who know and can appreciate the wonderful shades of feeling expressed in the *Messiah;* on Wednesday the light and shade were in still greater contrast, when some of the most popular solo writings, as, for example, the air from *Serse*, more familiarly known as the melody of the Largo in G, was most expressively sung by Miss Clara Butt as was the simple but most appealing air, "Lascia ch' io Pianga," from the opera *Rinaldo;* while those who find delight in the massive and stately choruses of *Israel in Egypt* must have been deeply moved by the excellent rendering of the immense choir on Friday. The festival is not only a joy at the time of performance, but for a long time the impressive numbers remain in the memory and afford the mind a delightful retrospect.

RETENTION OF MENSTRUAL FLUID IN ONE HALF OF A DOUBLE UTERUS.

WHEN this rare condition exists a mistaken diagnosis is very liable to be made. Menstruation occurs regularly from one half of the uterus, therefore the possibility of any retention does not occur to the practitioner. The following case, recently published by Dr. J. Lamond Lackie,[1] was at first mistaken for an early fibroid condition of the uterus with endometritis. An unmarried woman, aged twenty-four years, had suffered for six years from pain in the right side, which was relieved only by a hæmorrhagic vaginal discharge every four months. After a few weeks the pain set in again and became gradually worse until once more relieved. Also, for a day or two every month between her normal periods there was an acute exacerbation of pain, and she felt as if she were going to be unwell, but there was no discharge until the four months had elapsed. The patient distinguished this discharge both from blood and that of ordinary menstruation. It was "more like brown paint." It always came on some days after an ordinary menstruation and continued for about three weeks. Examination showed well-marked bulging in the right fornix and fulness in the hypogastric and right inguinal regions. The patient then stated that she always observed a swelling in the right side before the hæmorrhage came on, which disappeared as it set in. She was kept under observation for seven weeks, during which increase in size and tenseness of the pelvi-abdominal swelling were noticed. The diagnosis was then thought to lie between a sessile ovarian tumour and a dilated tube. Vaginal aspiration was performed. The fluid obtained was of a dark chocolate colour, just like altered menstrual fluid. It consisted chiefly of altered blood corpuscles and pus. The patient recognised the fluid as of the same nature as that which escaped every four months. She remained free from pain or swelling for nearly two months, then there was recurrence. The tumour was incised from the vagina. On passing a finger into the cavity and a sound into the left half of the uterus the septum at the cervical level was found to be moderately thin; through this the sound was forced. The opening was enlarged by a pair of curved dressing forceps and a drainage-tube inserted

[1] Edinburgh Medical Journal, March, 1897.

Hosted by Google

Finally, the vaginal incision was sewn up, so that all discharge should pass through the tube. It did so for several days, during which irrigation was employed. In the course of a week she was perfectly well. The tube was retained and bougies passed to ensure patency. Ten days after the operation her normal period occurred; no discharge escaped by the tube, which protruded at the vulva. A fortnight later she menstruated again, but this time through the tube. At this period the amount was less, but accompanied by more pain. This sequence continued for three months, during which the patient remained quite well. Unfortunately, she was then attacked by rheumatism and succumbed to cardiac complications. The case is of great interest in several respects. The writer very aptly suggests as an explanation of the symptoms not commencing until the patient was eighteen years of age (menstruation began at sixteen) that it was only then that the right half of the uterus commenced the function of menstruation. The alternate menstruation of the two halves, which was demonstrated after the operation, but evidently occurred from the first, is a very curious phenomenon. It has, however, been previously observed in cases of double uterus. The emptying of the accumulated discharge of the right half every four months must have occurred through some imperfect communication only available when the tension became so great.

RESECTION OF THE STERNUM.

PROFESSOR W. W. KEEN, of the Jefferson Medical College, Philadelphia, has published in the *Medical and Surgical Reporter* two cases in which the sternum was partially resected on account of tumours. The first patient was a woman, forty-four years of age, whose left breast, together with several enlarged axillary glands and the fascia over the pectoral muscles, was removed for carcinoma in March, 1892. The muscles themselves did not seem to be involved and were left. The patient made a prompt recovery. In January, 1894, the sternum showed a slight bulging at the junction of the manubrium and gladiolus, and in the following month a small nodule was discovered in the right breast. In March, 1894, the sternal tumour had increased very much in size, and as the sternum, the cartilages of the second and third ribs, and the intercostal muscle between them all seemed to be involved, both the cartilages and also the intercostal tissues were removed down to the pleura. The internal mammary artery was divided and secured by a curved needle passing through the thinned wall of the pleural cavity. A considerable portion (about 1 in. by 1½ in.) of both the manubrium and the gladiolus was then removed by the double rongeur forceps until apparently healthy bone was reached. The right breast was also removed, together with a layer of the pectoral muscle and all its fascia, and the right axilla was cleaned out. The patient recovered from the operation, but the disease returned, and she died in the following August. The second patient was a woman, twenty-eight years of age, in whom the tumour commenced in the beginning of 1895. In November, 1895, it covered the end of the right clavicle and the upper left portion of the manubrium, and there were two small nodules over the end of the right sterno-mastoid. It was diagnosed as sarcoma. The operation commenced with the removal of the lower third of the sterno-mastoid, together with all the diseased tissues in front of the sternum and clavicle. The inner third of the right clavicle and one inch of the inner end of the first rib were then removed, the manubrium was separated with the finger from the tissues of the mediastinum and divided just to the left of its right border and horizontally just above the joint between it and the gladiolus. The patient was discharged from hospital in January, 1896; no return has occurred after more than fifteen months, and her general health is now excellent. Portions of the sternum have frequently been removed for fracture, especially gunshot fracture, but Professor Keen has only been able to collect seventeen other cases in which the entire thickness of the bone was resected for tumour, not including superficial resections for such conditions as exostosis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AT the meeting of Fellows on July 1st only two resolutions will be brought forward. They are both to be introduced by Mr. R. B. Anderson, and refer to the refusal on the part of the Council to afford him pecuniary support in prosecuting his attempt to obtain a reversal of the judgments against him.

THE WALSALL SCHOOL BOARD AND MEDICAL CERTIFICATES.

THE Walsall School Board has unanimously carried the following resolutions:—

"That two medical men, Mr. Willmore (Walsall) and Dr. Martin (Bloxwich), be appointed, at a fee of 1*s.* 6*d.* in each case, to examine (1) children alleged to be absent from school on account of illness, and whose parents plead poverty as a reason for not obtaining a medical certificate; (2) children alleged to be absent from school on account of illness, whose parents have produced a medical certificate the genuineness of which the board have reason to doubt; (3) all candidates and pupil teachers on admission, as well as in special cases; and (4) to attend at the police-court when necessary and give evidence in relation to any of the cases which have been examined."

This is all very well, and we have no doubt that certificates must be examined by competent authorities occasionally, but we see no provision for letting the original signer of the certificate know that his certificate is to be supervised. As we said over and over again in the case of the London School Board, there is no objection to certificates being revised if the original giver is advertised of the fact, but to do so behind his back without letting him know is unpardonable, and if the Walsall School Board do not make provision for such a courtesy we can only advise every medical man in Walsall to refuse to give any certificate for a School Board.

ALLEGED EXTRAORDINARY HYPERPYREXIA.

SURGEON-MAJOR TUOHY relates the following case in the *Indian Lancet* of May 16th, 1897. A nurse, aged thirty-eight years, contracted typhoid fever whilst attending a case. On the thirteenth day, at 6.30 P.M., whilst the temperature was being taken in the mouth, the thermometer burst at the bulb, with the mercury at the top of the column registering 112° F. At 10.30 P.M. the temperature in the axilla was 112°, the pulse 120, the face dusky and anxious, the breathing rapid and shallow, but the mind perfectly clear. With such a temperature for four hours he regarded the case as hopeless and ordered a wet pack. In half an hour the temperature fell to 98° F. and the patient was put back to bed, feeling drowsy and tired. This extraordinary rise of temperature occurred many times before convalescence was established. On four occasions it reached 117°, and on two of these the thermometer burst, so that a still higher point must have been attained. Once, when the temperature was 114°, another medical officer, Surgeon-Major Ward, verified the observation. For weeks the temperature was taken every quarter of an hour, as the rise was often very sudden. The wet pack was always promptly employed, to which the writer attributes the recovery of the patient. We must say that we view this case with a good deal of reserve. Cases of extraordinary hyperpyrexia have been from time to time brought before medical societies, but always received with suspicion. Patients have been known to cause

Hosted by Google

elevation of the mercury in various ways, such as inversion, friction, the application of poultices or hot-water bottles. Dr. Stephen Mackenzie exposed a case of this kind where a temperature of 120° was registered, by placing two thermometers in the same axilla, and finding a difference of several degrees between them.[1] The subjects of extraordinary pyrexia have almost invariably been females, and often neurotic or hysterical. However, it would be going too far to assert that all were necessarily cases of deception. Many years ago the late Mr. John Teale published a case of "Excessive and Long-continued High Temperature after Spinal Injuries, with Recovery,"[2] in which the temperatures ranged up to 122° F. In this case special thermometers were used, and every source of fallacy was apparently guarded against. In commenting on the case at the time, we had to admit that he had answered all objections. The subject is certainly one requiring further investigation.

A CASE OF SEVERE DERMATITIS FOLLOWING TWO EXPOSURES TO THE X RAYS.

ON June 14th M. d'Arsonval presented to the Academy of Sciences at Paris a case, which had occurred in the practice of Dr. Apostoli, of dermatitis following two exposures to the x rays. The exposures were made upon May 22nd and 28th, 1896, the duration of the first sitting being forty minutes, with the Crookes's tube at a distance of fifteen centimetres from the skin, and the second lasted ninety minutes, the tube being at a distance of nine centimetres. After the first sitting nothing was noticed except great nausea on the part of the patient. After the second, however, an erythema appeared over the area which had been exposed—namely, the abdominal wall—and this erythema was followed by vesication and an abundant serous discharge. These gradually healed, and by July the patient was nearly well; but in August the whole of the affected surface sloughed and a severe burning pain was felt. No application to promote healing had the slightest effect and skin grafting was equally useless. At the end of October, 1896, the application of a current of oxygen was tried and promoted healing in a slight degree. In February, 1897, electric treatment was commenced. Statical electricity was used at first alone and then in combination with high frequency currents. In April, 1897, electric baths were commenced and employed twice a week, the current employed being the undulatory form. These applications had a very good effect, and by June, 1897, the whole affected surface, which measured 17·7 by 13·6 centimetres, was soundly healed. Dr. Apostoli considers that this form of dermatitis may be produced by the tube being too near, the sittings being too long, or even when short if following one another too rapidly or being too many in number. The dermatitis is very slow in healing, and apparently the best method of treatment is the employment of electric currents, both locally by using statical and undulating currents and generally by the exposure of the patient to a high frequency current.

IT is with great regret that we have learned of the deaths recently of two prominent members of the medical profession in New York. Dr. J. Lewis Smith, the well-known authority on diseases of children, died on the 9th inst., an Dr. William Lusk, the Professor of Midwifery at Bellevue College, on the following Sunday.

THE Abernethian Society of St. Bartholomew's Hospital will hold its mid-sessional meeting in the medical theatre of the school at 8 P.M. on July 1st, when Dr. Norman Moore will give an address on the Deaths of the Kings of England. All old members are cordially invited to attend the meeting.

[1] Medical Times and Gazette, Nov. 5th, 1881.
[2] Vide THE LANCET, March 6th, 1875.

THE annual general meeting of the Brussels Medical Graduates' Association will take place at the Café Royal, Regent-street, W., on Thursday, July 15th, at 6.30 P.M. At 7.15 for 7.30 P.M. the members and their friends will dine together, and Sir John Williams, Bart., Mr. Rentoul, Q.C., M.P., and Dr. A. E. Sansom will be the guests of the Association. Any Brussels medical graduate wishing to be present at the dinner is requested to communicate with the honorary secretary, Dr. Major Greenwood, at 12, New-court, Lincoln's-inn, W.C., or at 243, Hackney-road, N.E.

MISS JANE HARRISON, LL.D., the well-known authority on Greek antiquities, will give a lecture upon "Hospital Life in Ancient Greece," on July 8th, at 3.30 P.M., at the South-West London Polytechnic, Manresa-road, Fulham. Tickets may be obtained from the honorary secretary, University Extension, at the above address, and the proceeds will be devoted to the Extension evening classes.

THE authorities of the London Post-graduate Course have arranged that daily classes in bacteriology and hygiene will commence on July 5th and end on July 10th. This will enable busy practitioners to compress the needful work into the shortest possible time. Particulars can be obtained from Dr. Fletcher Little, secretary, 32, Harley-street, W.

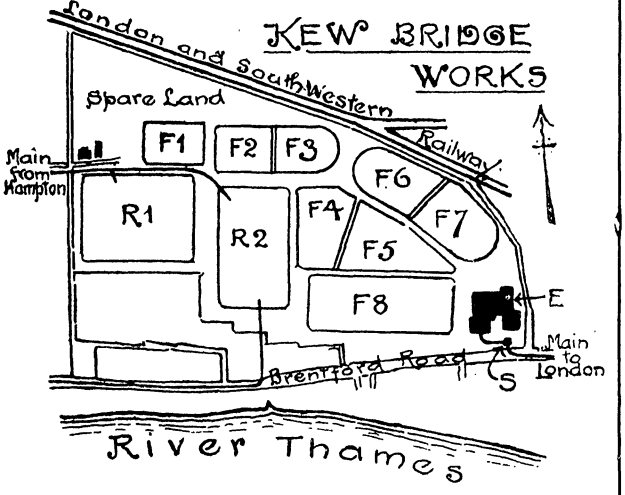
WE understand that Lord Lister has replied to the communication addressed to him by Mr. George Jackson, F.R.C.S. Eng., and three co-signatories, which appeared in our columns last week, and that he courteously declined to be placed in nomination for the approaching election to the Council of the Royal College of Surgeons of England.

T.R.H. THE PRINCE AND PRINCESS OF WALES have consented to open the Park Hospital, Hither-green, the new hospital of the Metropolitan Asylums Board, on Monday, July 12th, at 4.15 P.M.

LITERARY INTELLIGENCE.—We have received a copy of a new illustrated fortnightly Italian journal. It is published in Florence and called *Scena Illus rata*. The illustrations are well printed. Among the list of contributors to the letterpress are the names of Professor Baccelli and Professor Lombroso among scientific men, and among the purely literary names those of Daudet, Coppée, and Zola, so that the literary part of the paper as well as the art department will evidently be of a high order.

PRESENTATIONS TO MEDICAL MEN.—Mr. Charles W. Izod, medical attendant to H.R.H. the Duchess of Albany, who, as recorded in THE LANCET of June 12th, has been celebrating his jubilee of practice and residence in the village of Esher, was on June 16th, presented with a massive silver salver and three handsome silver bowls by the residents of Esher. The presentation was made by Mr. P. M. Martineau at a public meeting of the inhabitants. Each of the pieces of plate bore the recipient's crest and the inscription: "Presented by his many friends to Charles William Izod, on the completion of fifty years' medical practice in Esher. June 16th, 1897." Mr. Izod, who has also received a silver cup from H.R.H. the Duchess of Albany, was presented with an illuminated album containing the names of the 500 subscribers.—Mr. Edward W. Parsey, M.B., B.C. Camb., has been the recipient, from the King's Norton Ambulance Corps, of an electro-plated biscuit tray, as a thank-offering for his lectures on first aid.—Mr. J. S. Montgomery, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Sandyford, Glasgow, who has acted as resident surgeon at the works of the Steel Company of Scotland, at Newton, during the past eighteen months, was entertained to supper and presented with a handsome timepiece, suitably inscribed, and a travelling bag, on his leaving the district.—Mr. J. H. Marsh, M.R.C.S. Eng., L.R.C.P. Lond., has been presented with a handsome quarter chiming oak clock by the members of the Trinity Wesleyan Sunday School Male Ambulance Class, Macclesfield, as a token of appreciation of his services.

Hosted by Google



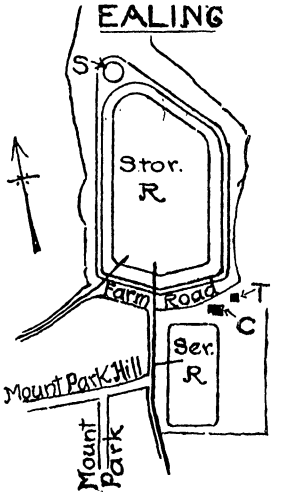
The Lancet Special Commission
ON THE
METROPOLITAN WATER-SUPPLY.

XVI.[1]
THE GRAND JUNCTION WATERWORKS COMPANY
(*Continued*).

Kew Bridge Works, Brentford (see B on Map and Fig. 1).—The Kew Bridge station is situated at Brentford in Middlesex. The area is about 26 acres. It consists of reservoirs, filter beds, and a pumping station, which are situated to the north of the Brentford road. There is a store yard and a house for the assistant engineer to the south of the road.

Reservoirs.—There are two reservoirs, an upper and a lower. The upper reservoir is capable of holding 14,000,000 gallons of water. Its depth in the centre is 14 ft. The slopes are lined with brick and concrete, and the bottom and sides are puddled. The lower reservoir is situated at a level of 8 ft. below the other. Its depth in the centre is 10 ft. It is capable of holding 8,000,000 gallons. The upper reservoir is supplied by both the 33-in. mains. The lower reservoir is supplied from both mains and also from the upper reservoir, from which the water flows to it in the form of a cascade.

FIG. 1.



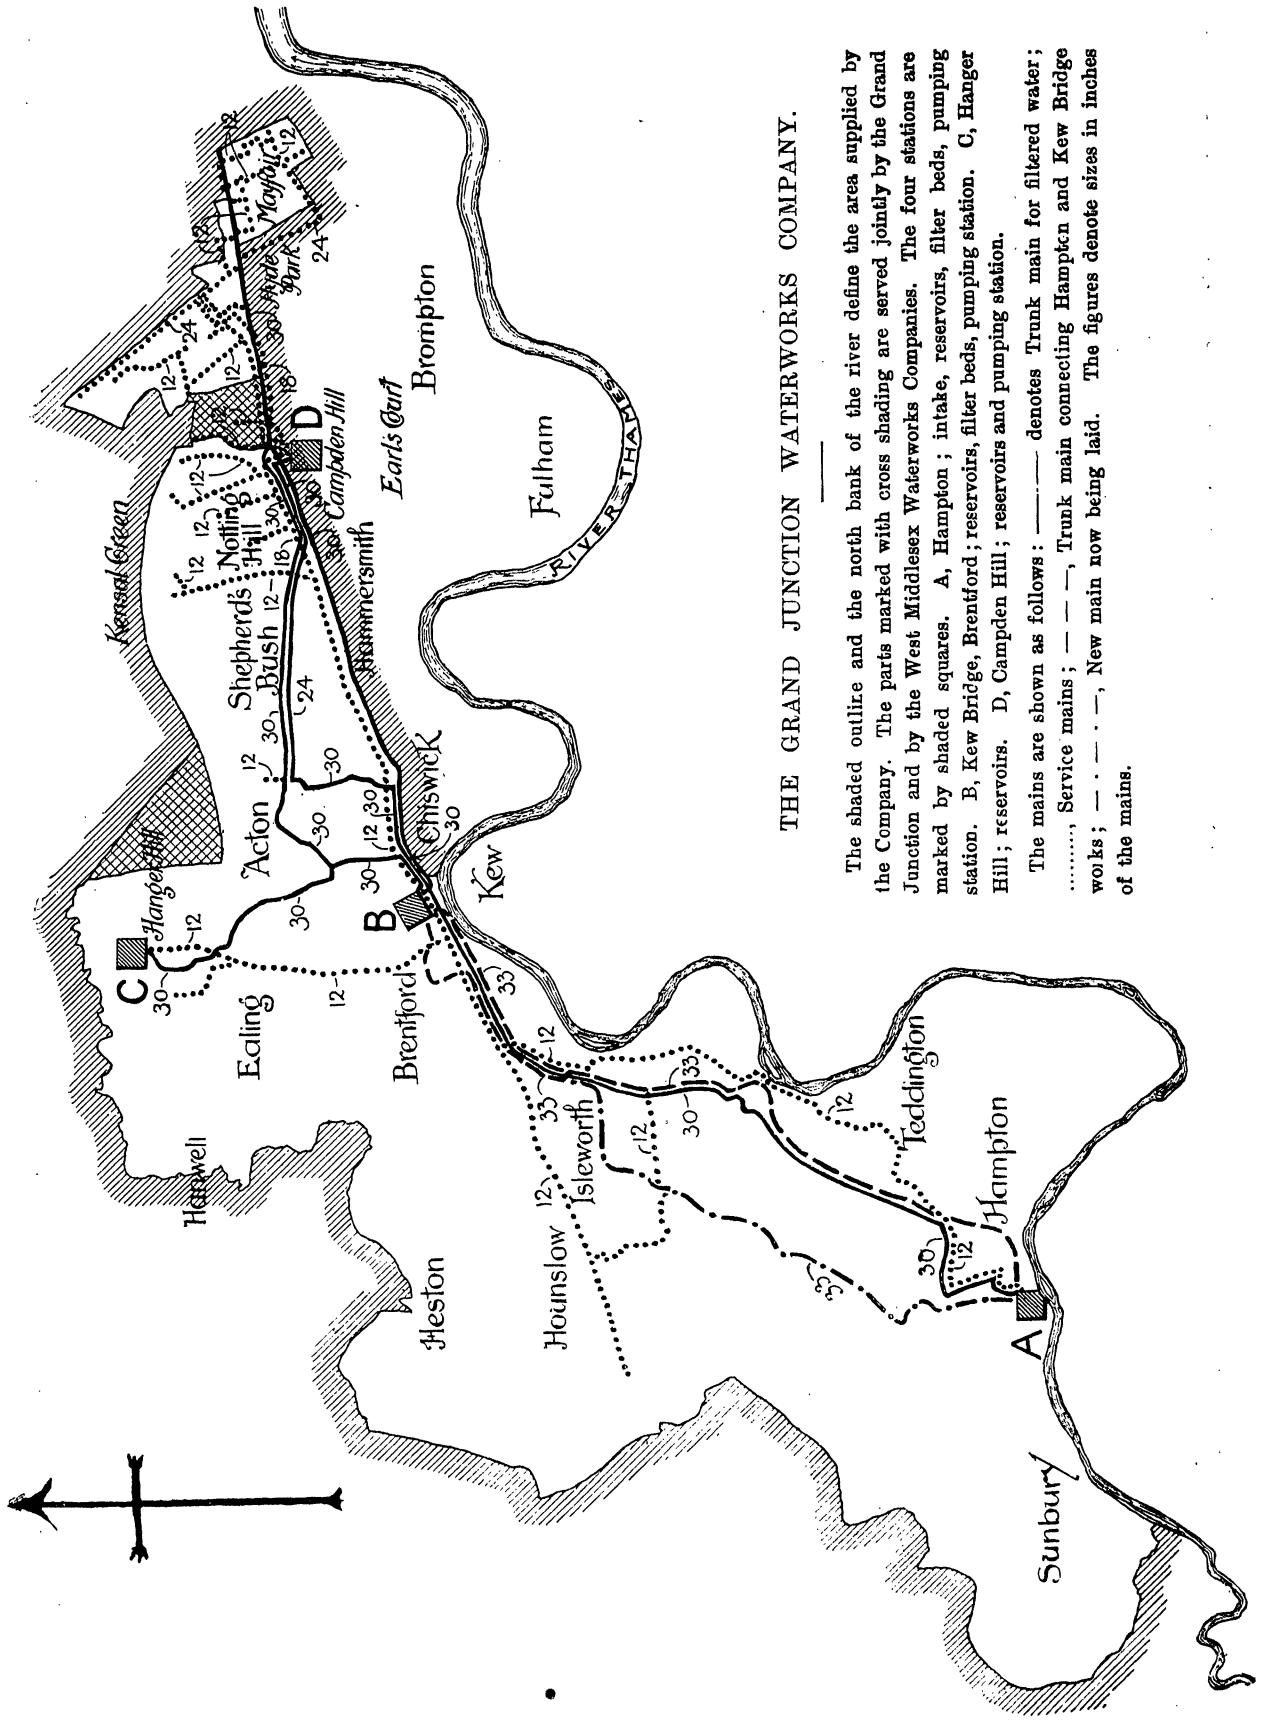
Kew Bridge Station, Brentford.—R 1, R 2, Reservoirs. F 1 to F 8, Filter beds. E, Engine-house. S, Standpipe tower.

Filter beds.—There are eight filter beds which have a total area of about 8½ acres. They are of somewhat irregular shape, but they are constructed on the same lines. They have from 2½ ft. to 3 ft. of sand and from 2 ft. to 2 ft. 6 in. of ballast. The only differences in them consist in the arrangements for the collection of filtered water, the presence or absence of ventilators, and the fact that two of them possess large filtered water chambers beneath. Filter No. 1 has an area of ¾ acre, it has a central filtered water channel and a small ventilation pipe in connexion with the filtered water channel on one side. Filters Nos. 2 and 3 have chambers for the storage of filtered water beneath them. These are covered with brick arches, the upper parts of which form the floors of the filter beds. Each is capable of holding 1,000,000 gallons. No. 4 has an area of 1¼ acres. The arrangement for collecting filtered water is by means of ballast. There are no drain-pipes at the bottom. Two air ventilators are situated over the filtered water culverts. No. 5 has an area of 1¼ acres. There are ventilators at the sides and one central one in communication with the filtered water channel. No. 6 has an area of ⅞ acre and it has no central air shaft. No. 7 has an area of ⅞ acre and two ventilating shafts. No. 8 has an area of 1⅞ acres. It has three large air shafts built of brick communicating with the filtered water culvert. The water from all the filter beds passes into a well situated near the engine-house, and from this it is conducted to the various engine wells.

Pumping arrangements.—A Worthington engine, capable of pumping 5,000,000 gallons a day, is used for the supply of the London district. It is worked at a pressure of 125 lb. The head of water worked against is 180 ft. This engine pumps 104 gallons per stroke, and the rate at which it is worked is 35 strokes per minute. A Cornish engine of the Bull type, having a cylinder of the diameter of 70 in. and a stroke of 10 ft. (and which therefore pumps 253 gallons per stroke), is worked at the rate of 12 strokes per minute. A Cornish pumping-engine, having a cylinder 65 in. in diameter and a stroke of 10 ft., pumps about 2,500,000 gallons a day to Ealing, working against a head of 235 ft. This pump is worked at a rate of 12 strokes per minute. Another engine, called the East Cornish, is also used for pumping to Ealing. This engine has a cylinder of 65 in. and a stroke of 9 ft. An engine called the West Cornish is used for pumping to the London district. It has a cylinder of 65 in., and pumps 140 gallons per stroke, usually working at a rate of 14 strokes per minute. The steam for the Worthington engine is generated by a water-tube boiler, and the engine is worked at a pressure of 125 lb. The other engines are worked by steam, generated by fifteen Cornish and one Lancashire boilers at a pressure of 40 lb. Two other engines called the "Ninety" and "The Hundred," are used for pumping to London. Of these, the cylinder of one is 90 in. and the stroke 10 ft. 6 in. The diameter of the cylinder of the other engine is 100 in. and it has a stroke of 11 ft. The water pumped by the Cornish engines passes through a stand-pipe 200 ft. in height. The stand-pipes are situated in a brick tower. There are two pipes for conducting water up and two for its return, and an overflow pipe. The rising main is 6 ft. in diameter at the base and the return pipe 3 ft. The Worthington engine pumps directly into the main. The station contains a cottage and a large workshop. There is also a store yard situated to the south of the Brentford-road next to the river, the site of the former intake of the Company.

Hanger Hill, Ealing (see C on Map and Fig. 2).—This

FIG. 2.



Hanger Hill Station.—S, Strainer. Stor. R, Storage reservoir. Ser. R, Service reservoir. C, Cottage. T, Tower.

station is situated at the highest point of Hanger Hill, 200 ft. above ordnance datum. It consists of two uncovered reservoirs and a tower containing a cistern. The high service reservoir is concreted at the sides and bottom and lined at the upper part with blue Staffordshire bricks. It is capable of holding 3,000,000 gallons of water. There is another reservoir of which the top water level is 7 ft. below that of the one just described. It is capable of holding 54,000,000 gallons. Its depth in the middle is 35 ft.

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., and XV. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, and June 19th respectively.

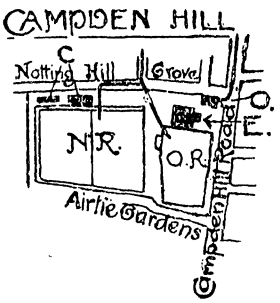
THE GRAND JUNCTION WATERWORKS COMPANY.

The shaded outline and the north bank of the river define the area supplied by the Company. The parts marked with cross shading are served jointly by the Grand Junction and by the West Middlesex Waterworks Companies. The four stations are marked by shaded squares. A, Hampton; intake, reservoirs, filter beds, pumping station. B, Kew Bridge, Brentford; reservoirs, filter beds, pumping station. C, Hanger Hill; reservoirs. D, Campden Hill; reservoirs and pumping station.



The mains are shown as follows: —·—·— denotes Trunk main for filtered water; ....., Service mains; — — —, Trunk main connecting Hampton and Kew Bridge works; — · — · —, New main now being laid. The figures denote sizes in inches of the mains.

Hosted by Google

Its shape is somewhat irregular, the sides slope as 1½ is to 1, they are lined with concrete for the lower 10 ft. and above with pressed bricks laid on edge and set in cement on a concrete bed. This reservoir is provided with an outlet tower fitted with five valves placed at different heights, so that water can be drawn off at some point a few feet below the surface of the water, no matter at what level the height of the surface of the water may be. Water for the supply of this reservoir is pumped from Kew. Before it is distributed it passes through a strainer. The strainer is in reality a filter bed. It is a circular shaft 60 ft. in diameter and is provided at the bottom with 2 ft. of fine shingle. Before distribution all the water from this reservoir passes through the strainer. The reservoirs are separated one from the other by a public road; both are fenced in. Near the high service reservoir there is the tower containing a cistern of which the outside dimensions are 16 ft. by 16 ft. by 8ft. The water is pumped into it by a small gas-engine. This water is used for the high service supply of the houses in the immediate neighbourhood. A caretaker's cottage is situated here.

Campden Hill (see D on Map and Fig. 3).—This station is situated 130 ft. above ordnance datum on the highest part of Campden Hill, just to the north of Airlie-gardens and next to the Campden-road, which separates it from the reservoirs of the West Middlesex Water Company. There are three covered reservoirs, a pumping-station, three cottages, and an office. The total area is about five acres. The reservoir which was first constructed (see Fig. 3, O R) is covered with brick arches built on iron girders, which are supported by brick arches. It is ventilated by means of iron shafts. The bottom of the reservoir is lined with concrete, and the sides slope 1 in 4. The capacity of the reservoir is stated to be 4,000,000 gallons. The top is covered by a thin layer of earth and turfed over. The two newer reservoirs (see Fig. 3, N R) are covered with arches built on brick piers, and are ventilated by perforated bricks at the sides. The slope of the sides of these reservoirs is less oblique than those of the older one. The maximum depth of water to which they are filled is 19 ft., and they are stated to have a capacity of 7,000,000 gallons each. The western reservoir and part of the middle one are partly covered with concrete, and the top is let to a lawn-tennis club.

FIG. 3.

Campden Hill Station.—C, Cottages. O, Office. E, Engine-house. N R, New reservoirs. O R, Old reservoir.

The pumping arrangements.—There are three Cornish engines. Of these, two have cylinders 70 in. in diameter and a stroke of 10 ft. The third engine has a cylinder 90 in. in diameter and a stroke of 10 ft. At the present time one of the two smaller engines only is in use. When visited on June 2nd it was working at a rate of about eight strokes a minute against a head of water of 115 ft. There are nine Cornish boilers, of which three were in use, and the pressure worked at was 40 lb. The water is pumped into a standpipe, of which the top is 288·4 ft. above ordnance datum. The standpipe is situated in the tower which is such a conspicuous object on Campden Hill. The amount of water pumped from this station during the last week was 12,000,000 gallons. The high pressure is obtained for the high-service supply of Maida-vale and the Park-lane district.

Communications with other companies' mains.—The mains of the Company communicate with those of the West Middlesex, the Chelsea, and the East London Waterworks Companies; with the West Middlesex Company's by a 24-in. main in Edgware-road, opposite Kilburn Park-road; with the West Middlesex Company's from the same 24-in. main into a 21-in. main at the junction of Edgware-road and Bayswater-road; with the Chelsea Company's 24-in. connexion at Hyde Park Corner; with the East London Company's connexion from the 36-in. main into Kew works; and with the East London Company's mains into service mains in the Grand Junction-road and neighbourhood.

Length of new pipes.—The length of new pipes ranging from 3 in. to 7 in. laid in 1895 was 4762 yards, and during the year 1896 was 9516 yards.

Hydrants.—The number of hydrants erected during the year 1895 was 35, and during the year 1896 it was 8.

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 59 443; on Dec. 31st, 1895, 60,150; and on Dec. 31st, 1896, 60 910.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 100.

Highest supply given.—The highest supply given is at about 200 ft. above ordnance datum.

each of these will have an area of one and a half acres. 2. An engine-house fitted with a Worthington engine is being erected for pumping water to Kew. 3. Two reservoirs are being converted into filter beds of one acre each. 4. A new main is being laid between Hampton and Kew Bridge (see Map).

AREA OF SUPPLY.

The Act of 1852 authorises the Grand Junction Company to supply the following places, two of which are entirely and the others partly supplied by the Company:—

Supplied.—Brentford, Ealing.

Partly supplied.—Hammersmith, Kensington, St. Mary Abbotts, Paddington; St. George, Hanover-square, St. James Westminster, and St. Marylebone.

The Act of 1861 authorises the supply of the following places, almost all of which are entirely supplied by the Company:—Acton, Bushey-park, Chiswick, Hampton, Hampton Court, Hampton Wick, Hanworth, Isleworth, Teddington, Twickenham, and Whitton. (Hampton Court Palace has a separate and private supply.) Parts of Ealing and Isleworth were excluded by this Act. The Act of 1878 authorises the supply of Heston and Hanwell (which are entirely supplied by the Company) and the previously excluded parts of Ealing and Isleworth.

Errata.—We regret that some errors should have crept into the first part of this article. On p. 1702, fifth line from the bottom of the right hand column, for "; D D" read "D ,D'". On p. 1704, fifteen lines from the top of the left hand column, for "Fig. 3 B." read "Fig. 3 D D." The full description of Fig. 3 should read as follows:—Diagram of ground plan of the arrangements for collecting water from the gravel bed. A, B, filter bed into which the river water is introduced. C, C, collecting pipes. D, D, D, D, brick shafts. The two at the lower part of the diagram represent the ones which discharge the water into the main which conducts it to the engine-house.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Surgery of the Bladder.

MR. FRANCIS M. CAIRD, F.R.C.S.Edin., Lecturer on Surgery, Assistant Surgeon to the Royal Infirmary, Edinburgh, delivered a lecture before the Royal College of Surgeons of Edinburgh on June 11th, entitled a Contribution to the Surgery of the Bladder. The address was devoted mainly to a consideration of recent advance in the treatment of tumours of the bladder. The lecturer contrasted the ease with which an accurate diagnosis could be established in the case of vesical tumours by means of the cystoscope with the greater difficulties encountered in formulating an opinion in gastric cases. In the latter instance the line of treatment had been systematised; in the former, despite the greater facilities for diagnosis, it is still uncertain. While the uniformly fatal issue of tumours of the bladder has long been recognised surgical intervention is of very recent date, for only fifteen years ago the general practice was to rely upon internal medication and the unstinted use of opium. A great advance was made when the value of drainage of the bladder became established, since by this means the suffering was markedly lessened and the hæmorrhage became arrested. Of such palliative measures examples were given. The advantages of suprapubic drainage lay in the shortness of the route, the unimportance of the tissues traversed, the remoteness of the wound from septic channels, and the ease with which a permanent tube might be applied. Again, the site of the tumour in the majority of cases is left undisturbed. Radical measures, complete removal of malignant growths, should in every case be the surgeon's object. When the ureters are not affected and the peritoneum can be stripped from the viscus, the whole thickness of the bladder-wall may readily be excised; when the peritoneum cannot be separated the method of Clado should be adopted. In all cases where possible the vesical wound should be sutured. If one ureter be alone affected, its mouth may be removed along with the tumour, and the divided extremity may be successfully re-implanted at a new site in the sutured bladder, or if this be impossible it may be led into the colon or rectum. The implication of the floor of the bladder or of both ureters generally requires complete extirpation of the organ. In the female this operation has been carried out with success on three occasions, the ureters being implanted in the vagina, which was closed so as to form a reservoir with the urethra utilised as an outlet. In the male, greater difficulties present themselves. The ureters have been led into the open wound or grafted into the great gut. It has now been sufficiently demonstrated that the latter method is possible and practicable. The rectum tolerates the urine and the sphincter is equal to the task, so that continence is easily maintained for three or four hours without inconvenience. There are six successful cases reported of bilateral implantation of the ureters for extroversion, and it is sufficiently clear that where other methods are not available the grafting of a single ureter in cases of rupture, &c., or of both in cases of extroversion or preliminary to excision of the bladder is sufficiently justifiable. It was suggested that an attempt might be made to establish an artificial bladder by the occlusion of a segment of the sigmoid flexure and providing it with a valvular outlet to serve as a urethra after the manner of Witzel. At a subsequent date the ureters may be implanted and the bladder may be excised. Reference was made to the various methods of uniting the ureters to the intestine, and the button devised by Boari for this purpose was demonstrated. Special stress was laid upon the value of the Trendelenburg position, the use of Petersen's bag, and Cathcart's method of continuous suction drainage.

The lecture was illustrated by specimens, anatomical and pathological, from the museum of the College. At its close the lecturer was complimented by the President, Emeritus Professor Struthers, on the clearness of the exposition and on the ingenuity of his methods of dealing with the various morbid conditions of the bladder. He had listened with the greatest interest to the lecture, for all these operations were new since he was in surgery, as surgeon to the old Royal Infirmary, from thirty to forty years ago. At that time they approached the bladder only from below. To attack it from above the pubes was regarded as likely to be attended by a fatal result. Thanks to Lord Lister, all these wonderful operative procedures are now rendered possible. The President mentioned that Mr. Caird's lecture concluded the series of College lectures for the present session.

STATISTICS OF SMALL-POX AND VACCINATION.

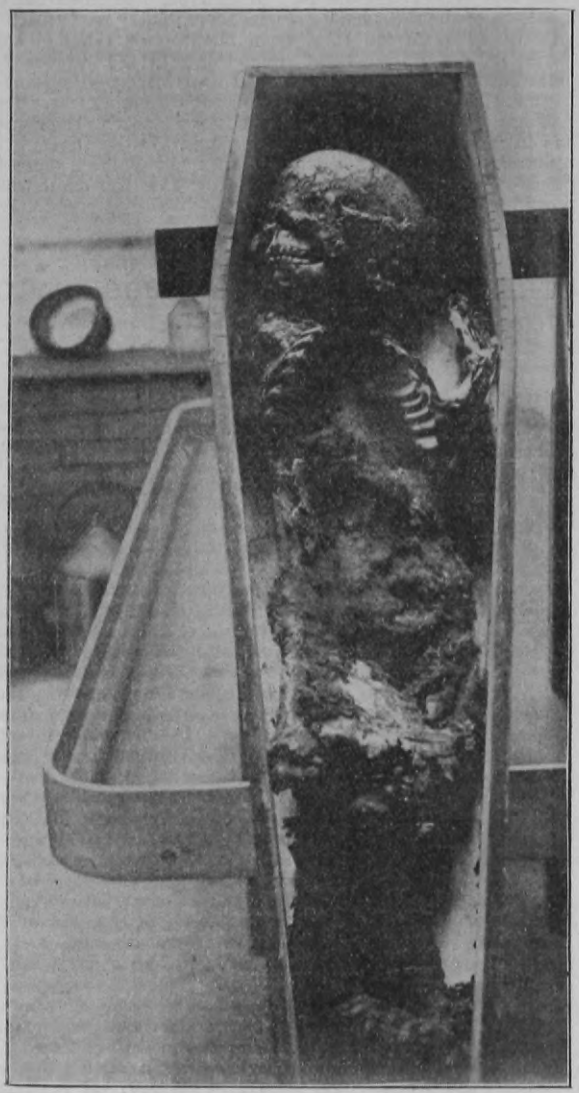
ON June 15th Mr. Alfred Milnes, M.A.Lond., read a paper before the Royal Statistical Society on "Statistics of Small-pox and Vaccination, with Special Reference to Age-incidence, Sex-incidence, and Sanitation." The paper was understood to be a rejoinder to a paper on the same subject by Mr. Noel A. Humphreys read before the same society a few months ago. The main interest attaching to Mr. Milnes's paper arises from the fact that he is the editor of the *Vaccination Enquirer* and one of the most influential advocates of the party which absolutely refuses to recognise any protective effect from vaccination. That he is an able advocate of this incomprehensible tenet will probably be admitted by all who possess the patience to read carefully his long and elaborate paper; and it is in some respects useful to know what can be said in support of anti-vaccination by one of its most skilful exponents. It is impossible, however, to assert that the paper contains much that is new in the way of argument although many of the well-worn theories and assertions of Mr. Milnes's party are handled with exceptional skill. The paper carefully avoided all but the most incidental reference to the recent remarkable epidemic of small-pox in Gloucester; and Mr. Milnes, when asked during the discussion which followed the reading of the paper for an explanation of this omission, declared that the whole of the facts of that epidemic are still under dispute, and that he does not believe any of the figures that have yet been published relating to it! This remark indicates the tone and spirit of much of the paper, which it is needless to say is objectionably aggressive. It is asserted that "vaccination and small-pox attained their maximum together, and together they have steadily declined." This is not strictly accurate, because infant vaccination reached

Hosted by Google

its maximum in 1876, which was certainly not the year of maximum small-pox mortality. Moreover, there is no reasonable ground for expecting that an annual default of 14 or 15 per cent. in the official returns of infant vaccination would immediately cause an increaseed small-pox mortality, unless small-pox were prevalent at the time, as was the case recently at Gloucester.

The comparison of the declining rates of mortality from other diseases than small-pox was dealt with at great length by Mr. Milnes. Because fever and cholera have declined concurrently with the decline of small-pox he argues that there is no justification for attributing the decline of small-pox to vaccination. He refuses to recognise that fever and cholera are diseases distinctly due to insanitary local conditions, and that no one would venture to assert that small-pox can be produced by the same causes. Mr. Milnes is extremely autocratic in his methods of dealing with facts. With a view to mask the remarkable decline in the proportional child mortality from small-pox in recent years, he insists on treating all deaths ascribed to chicken-pox as fatal cases of small-pox; and he further insists, with a view to increase the proportion of small-pox deaths after vaccination, that all the cases of small-pox registered with "no statement as to vaccination" are vaccinated cases. The omission on the part of certifying practitioners to give this information for insertion in the death register is much to be regretted, but Mr. Milnes's assertion that all the "not stated" cases are vaccinated cases is unjustifiable and certainly incorrect, as the "not stated" cases include large numbers of cases in which the deceased persons, although reported to be vaccinated, bore no marks of the operation.

Mr. Milnes devoted a considerable portion of his paper to the elaboration of the pet theory of the opponents of vaccination that sanitation and not vaccination is the controlling factor of small-pox mortality. Because Dr. Farr's life table of diseases shows that small-pox mortality in 1861–70 was far lower in the healthy (that is, the rural) districts than in Liverpool it is asserted that sanitation rather than vaccination governs the mortality from this disease. In another part of the paper it is admitted that "small-pox is a question of exposure to infection," and yet Mr. Milnes does not recognise that this undoubted fact vitiates his conclusions from the small-pox rates in healthy districts and in Liverpool. What is the relative chance of exposure to infection in a healthy rural district and in a seaport town like Liverpool?



Mr. Noel A. Humphreys, in his recent paper, gave a table showing that the proportion of child mortality from small-pox at each of the six recent local epidemics investigated by the Royal Commission on Vaccination bore a constant relation to the amount of default of infant vaccination in preceding years. In Warrington and Sheffield, where the default of vaccination was under 5 per cent., 23 and 26 per cent. of the deaths from small-pox were of children under ten; while in Gloucester and Leicester, where the default was 68 per cent., the proportion of small-pox deaths under the age of ten years was 65 and 71 per cent. respectively. These facts appear to have disturbed the opponents of vaccination, and Mr. Milnes, as the result of elaborate calculation, comes to the conclusion that the "high proportion of children's deaths in Leicester is due to the high proportion of children's attacks!" This cannot be questioned, but had neglect of vaccination nothing to do with the high proportion of children attacked? We more than suspect that it had in Leicester and also in Gloucester, where 280 children under ten years of age died from small-pox last year.

Mr. Milnes, with reference to the sex-incidence of small-pox, asserts, with a view to depreciate the value of re-vaccination, that "there can be no doubt that re-vaccination is preponderatingly incident on the male sex." We venture very much to doubt the probability of the accuracy of this assertion, for notwithstanding the compulsory re-vaccination of the army and navy, and of the postal service, very large numbers of female domestic servants are undoubtedly re-vaccinated, and it is easier to persuade women than men to be re-vaccinated. It would be interesting to have some actual figures and experience on this point, on which Mr. Milnes seems to think there is no room for doubt. There can, however, be practically no question about the fact that adult males, who appear to suffer from small-pox more severely than adult females, are as a rule exposed to greater risk of infection than females, and if this, o a higher case-mortality of small-pox among males, be the cause of the greater liability of males to fatal small-pox, what becomes of Mr. Milnes's attack on the value of re-vaccination?

At the close of Mr. Milnes's paper, a short discussion followed in which Mr. Noel A. Humphreys, Dr. W. R. Hadwen, Mr. Shirley Murphy, Mr. Yule, Dr. E. J. Edwardes, and one or two others took part, and the usual vote of thanks to the reader of the paper was passed.

THE DISCOVERY OF HUMAN REMAINS IN MARYLEBONE.

BY the kind permission of Dr. G. Danford Thomas we are enabled to publish the accompanying illustration, taken from a photograph of the remains of a body found in a disused house in Little Marylebone on March 24th of this year. Workmen were engaged in pulling up the floor boards of the second-floor back room when they found the remains. The body was partially clothed in a child's shirt and bodice, which were much destroyed. There were also a pair of socks and a pair of boots in a good state of preservation. Under the body was a portion of the *Times* newspaper of Nov. 25th,

1879. A print dress was also wrapped round the body. The lower part was wrapped in American cloth. Mr. Spurgin, the divisional surgeon, who examined the remains, found that they were those of a female child between six and seven years of age. The temporary teeth were all present, and on removing

Hosted by Google

a piece of skin over the upper maxilla the first permanent molar could be seen in the ramus of the jaw behind the second temporary molar, these showing the value of dentition in identifying the age of a dead body. The child had been short and squat, as was evidenced by the length of the bones of the legs being out of proportion to that of the spine. There was a curvature of the spine, which might have been a natural deformity or due to the position in which the body had been placed after death. The cause of death had evidently been suffocation as a neckerchief of some silken or gauzy material was found pressed tightly over the mouth and the tongue was protruded between the teeth. The body was in a mummified condition, the skin of the head, face, and abdomen being of a leathery consistence. The parietes of the thorax had almost disappeared, and the contents of the thoracic cavity were represented by a heap of brown dust. The arms were separated from the body. The parietes of the abdomen were better preserved, brown in colour, and almost like parchment. The only organ of which there were any distinct traces was the liver, which was represented by a brownish mass about the size of a cricket ball. The bones were brown in colour and pliable, easily crumbling to dust. A peculiar odour was emitted, somewhat resembling that of old cheese. The fact that the leather boots were in good preservation would negative the supposition that the body had been partially eaten by rats. The mummified condition was probably due to the fact that the body had been laid in a dry place where there was free draught. The time that had elapsed since the body had been placed in the position in which it was found, Mr. Spurgin thought, must have been ten or twelve years at the least, but the date of the *Times* newspaper would suggest a good deal longer than that, as it is not a common thing for a newspaper to lie about for seven years, for, as above stated, the date of the *Times* found with the body was 1879, and there was nothing in the appearance of the body to negative the supposition that it had been there over seventeen years. The appearance presented by human remains after a lapse of time varies greatly, depending entirely upon surrounding conditions. In dry, elevated situations putrefaction goes on very slowly, and other cases are on record where the body of a child has been found in the rafters of a house in a mummified condition.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following letter has been sent to all the candidates for the vacant seats on the Council of the College.

West Hill, Putney, S.W.,
18th June, 1897.

DEAR SIR,—Understanding that you are a candidate at the approaching election to the Council of the College, the executive committee of this society has instructed me to ask you to be good enough to communicate your views on certain matters of interest to the Fellows and Members. In explanation of this request from those who are not directly electors, I am to refer you to a resolution passed by the Council in March, 1896, to the following effect: "That this Council represents the Body Corporate of the College, and therefore the Members as well as the Fellows." I am further to add that should you be good enough to favour me with a reply we propose to publish it, subject to your approval.

The Committee of this Society feels that it is desirable that in future the Fellows and Members should be in possession of something more than vague statements in the press as to the views of candidates on current topics.

The following are the questions to which I am directed to solicit a reply:—

1. Are you in favour of granting the Members a limited direct representation on the Council?
2. Do you consider that the President should be elected by the Fellows generally or as at present?
3. How do you think that the representative of the College on the General Medical Council should be appointed in accordance with the Act of 1858?
4. Will you support a literal interpretation of By-law 15, and do you consider that the rights, privileges, &c., of a Fellow or Member referred to in the By-law are those in virtue of which he practises his profession?

I remain, faithfully yours,
W. G. DICKINSON, Honorary Secretary.

Concerning the replies received up to date Mr. Dickinson writes to us as follows:—

"Mr. JACKSON replies 'yes' to the first question; to the second he answers that he thinks that the President should have been a member of Council for at least from two to three years, and should be elected by the reformed Council; the third question he does not answer clearly, and replies 'yes' to the fourth."

"Mr. HOWSE replies 'no' to the first question; 'as at present' to the second and third; to the fourth, which he objects to as 'vaguer than the by-law itself,' he says he will 'support any legal interpretation which seems to me just and good for the profession and the College.

"Mr. EDMUND OWEN prefers to reserve his freedom of action and independence as a member of Council if elected, and therefore declines to answer the questions.

"Mr. ANDREW CLARK coincides with the present policy of the Council, and is in sympathy with their resolution of March 16th.

"Mr. WATSON CHEYNE does not propose to pledge himself to any course of action if elected."

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

THE summer meeting of this society was held in Trinity College, Dublin, on June 10th and 11th. In addition to an unusually large number of British anatomists the following foreign guests were present:—Professor Waldeyer (Berlin), Professor His (Leipzig), Professor Leboucq (Ghent), Dr. Otis (Boston, U.S.A.), Professor Disse (Marburg), Professor Spalteholtz (Leipzig), Dr. de Bruyne (Ghent), Dr. Frohse (Berlin), and Dr. Kœstner (Leipzig). Professor G. D. Thane took the chair at 10 A.M. on the 10th, and after seven new members had been elected the following programme was carried out. Dr. T. H. Bryce, (Glasgow): a Pair of Negro Femora, the left showing a remarkable development of the popliteal surface. Professor Spalteholtz (Leipzig): Stereoscopic Photographs illustrating the Distribution of the Arteries of the Human Skin. Professor Leboucq (Ghent): the Ossification of the Terminal Phalanges of the Finger in relation with Hyperphalangy. Professor Birmingham (Dublin): Models illustrating the Topographical Anatomy of the Abdominal Viscera. Dr. Kœstner (Leipzig): Specimens of Malformed Chick Embryos. Professor Sir William Turner (Edinburgh): X Ray Photogtaphs of Mercurial Injections of the Arteries of the Limbs and Kidneys. Dr. Otis (Boston, U.S.A.): Some Points in the Structure of the Rectum. Professor A. Macalister (Cambridge): A Study of Australian Brains. Mr. J. Cantlie (London): On the Position of the Gall-bladder. Professor R. Howden (Durham): On a Case of Marked Distension of the Colon. Professor Redfern (Belfast): On the Development and Nutrition of Bone and Cartilage. In the afternoon at 2.30 P.M. the following papers were read: Professor Windle (Birmingham) and Mr. F. G. Parsons (London): Note on some Points in the Nomenclature of Comparative Myology. Professor W. Anderson (London): The Peritoneal Relations of the Sigmoid Flexure. Professor Disse (Marburg): The Development of the Olfactory Nerve in Birds. Professor Spalteholtz (Leipzig): Reticulated Tissue in Different Organs. Professor Dixon (Cardiff): The Development of the Eye-muscle Nerves in Mammals. Professor Cunningham (Dublin): (1) the development of the Sulcus of Rolando; and (2) the Development of the Calcarine Fissure. Dr. E. H. Taylor (Dublin): The Applied Anatomy of the Rectum. In the evening the members were entertained at dinner in the College of Physicians by the President of the Royal Academy of Medicine in Ireland. On Friday, June 11th, the meeting breakfasted with Professors Cunningham and Birmingham at the Zoological Gardens in Phœnix Park, after which the following communications were made: Professor v. Bardeleben (Jena) and Dr. Frohse (Berlin); The Finer Ramifications of Nerve Filaments in Muscle. Dr. C. J. Patten (Dublin): (1) Two Curious Modifications of the Lower Jaw; and (2) Cervical Vertebræ in which the Laminæ have not fused. Professor Cunningham (Dublin): Models and Specimens of the Kidneys. Dr. G. Elliot Smith (Sydney): The Morphology of the Fornix and Margin of the Cerebral Cortex. Dr. W. Smyth (Belfast): Absence of Pectoralis Major in a Living Boy. Dr. de Bruyne (Ghent): the Functional Adaptations of Phagocytosis. Professor Waldeyer: The Anatomy of the Outer Wall of the Pelvis, with special Reference to the Position of the Ovary. Dr. R J. Berry (Edinburgh): The Anatomy of the Cæcum and Vermiform

Appendix. Mr. Booth Pearsall (Dublin): The Linear Determination of the Human Tooth-Form. Dr. W. S. Haughton (Dublin): Applications of X Rays Photography to Anatomical Investigation. Professor D. J. Cunningham (Dublin): Note on Cape Hunting Dogs. Professor Windle (Birmingham): Priestley Smith's Formol Method of Mounting Specimens of the Eye. Professor R. Howden (Durham): On a Case of Bifid Scrotum.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are a few of the principal amounts received at the Mansion House, the lists of which have been received at THE LANCET Office up to the time of going to press on Thursday, when the total amounted to about £8000. The total sum recorded at the corresponding period last year was £17,000.

	£	s.	d.
St. Paul's Cathedral	593	3	4
Westminster Abbey	459	16	0
St. Michael, Chester-square	1326	0	0
Delta	200	0	0
E. O.	100	0	0
St. Matthew's, Brixton	106	9	2
Foundling Hospital Chapel	104	14	3
Union Chapel, Islington	134	8	2
Metropolitan Tabernacle	109	8	0
St. Nicholas Parish Church, Chislehurst	251	0	8
St. Margaret's, Westminster	239	19	6
St. Peter's, Brockley...	121	0	0
St. Stephen's, South Dulwich	202	6	5
Christ Church, Highbury	100	13	9

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6610 births and 3328 deaths were registered during the week ending June 19th. The annual rate of mortality in these towns, which had been 17·4 and 15·6 per 1000 in the two preceding weeks, rose again last week to 15·8. In London the rate was 14·6 per 1000, while it averaged 16·6 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in West Ham, 10·8 in Burnley, 10·9 in Hull, and 11·6 in Brighton; the highest rates were 21·6 in Huddersfield, 22·2 in Preston, 22·8 in Bolton and 26·9 in Salford. The 3328 deaths included 354 which were referred to the principal zymotic diseases, against 364 and 379 in the two preceding weeks; of these, 138 resulted from measles, 78 from whooping-cough, 49 from diarrhœa, 41 from diphtheria, 28 from scarlet fever, 20 from "fever" (principally enteric), and not one from small-pox. No death from any of these diseases was recorded last week in Swansea; in the other towns they caused the lowest death-rates in Bristol, Bradford, and Croydon, and the highest rates in Plymouth, Preston, Bolton, and Salford. The greatest mortality from measles occurred in Birmingham, Burnley, Preston, Bolton, Manchester, and Salford; from scarlet fever in Wolverhampton, from whooping-cough in Plymouth and in Huddersfield, and from diarrhœa in Salford and in Norwich. The mortality from "fever" showed no marked excess in any of the large towns. The 41 deaths from diphtheria included 29 in London, 3 in Liverpool, 2 in Burnley, and 2 in Sheffield. No fatal case of small-pox was registered either in London, or in any other of the thirty-three large towns. There were no cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 19th inst., the numbers at the end of the three preceding weeks having been 12, 4, and 2 respectively; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2670, against 2546, 2601, and 2637 on the three preceding Saturdays; 274 new cases were admitted during the week, against 278, 274, and 255 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 229 and 191 in the two preceding weeks, further declined to 141 last week, and were 94 below the corrected average. The causes of 43, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Leeds, Hull, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Preston, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 per 1000 in each of the two preceding weeks, declined again to 19·4 during the week ending June 19th, but was 4·5 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·9 in Perth and 16·1 in Greenock to 22·0 in Dundee and 27·0 in Leith. The 577 deaths in these towns included 29 which were referred to whooping-cough, 24 to measles, 23 to diarrhœa, 5 to scarlet fever, 5 to "fever," 1 to diphtheria, and not one to small-pox. In all, 87 deaths resulted from these principal zymotic diseases, against 93 and 94 in the two preceding weeks. These 87 deaths were equal to an annual rate of 2·9 per 1000, which exceeded by 1·2 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 40 and 37 in the two preceding weeks, further declined to 29 last week, of which 13 occurred in Glasgow, 5 in Edinburgh, 5 in Dundee, and 5 in Leith. The 24 deaths from measles were within 3 of the number in the preceding week, and included 15 in Edinburgh, 5 in Glasgow, and 3 in Leith. The deaths referred to different forms of "fever," which had been 3 and 8 in the two preceding weeks, declined again to 5 last week, of which 4 occurred in Glasgow, where 3 of the 5 fatal cases of scarlet fever were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 110 and 108 in the two preceding weeks, were 109 last week, and exceeded by 27 the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 28·3 to 22·4 per 1000, further fell to 19·7 during the week ending June 19th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 28·5 per 1000, the rate during the same period being 15·8 in London and 25·8 in Edinburgh. The 132 deaths registered in Dublin during the week under notice showed a decline of 18 from the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 10 and 14 in the two preceding weeks; of these, 6 resulted from whooping-cough, 3 from diphtheria, 2 from scarlet fever, 1 from measles, 1 from "fever," and 1 from diarrhœa. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 1·4 in London and 3·7 in Edinburgh. The fatal cases of whooping-cough, which had been 3 and 4 in the two preceding weeks, further rose to 6 last week. The 3 deaths referred to diphtheria exceeded the number recorded in any week since February last. The fatal cases of scarlet fever, which had been 2 and 4 in the two preceding weeks, declined again to 2 last week. The mortality from measles and from "fever" also showed a decline from that recorded in the preceding week. The 132 deaths in Dublin last week included 29 of infants under one year of age, and 24 of persons aged upwards of sixty years; the deaths of children showed a slight increase, while those of elderly persons were considerably below the number recorded in any recent week. Six inquest cases and 4 deaths from violence were registered; and 50, or more than a third, of the deaths occurred in public institutions. The causes of 6, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL JAMES has assumed Charge of the Station Hospital, Beverley, in relief of Brigade-Surgeon Hoystead.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions:—Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels:—*Bengal Establishment:* Edgar Geer Russell. *Bombay Establishment:* William McConaghy and Thomas Stephenson Weir. Surgeon-Majors to be Surgeon-Lieutenant-Colonels:—*Bengal Establishment:* William Owen, Walter Conry, George Jerome Kelly, Dharmadas Basú, Alexander William Mackenzie, Jeremiah Mullane, Douglas Ffrench-Mullen, James Alexander Nelis, Aylmer Martin Crofts, James Crofts, and William Coates. *Madras Establishment:* Henry Augustus Fitzroy Nailer, and Nityananda Chatterjie. *Bombay Establishment:* William Keith Hatch, Hormasji Dadabhai Masini, and Kanóbá Ranchoddás Kirtikar. Surgeon-Captains to be Surgeon-Majors:—*Bengal Establishment:* Francis James Drury, Herbert Jekyl Dyson, Frederick Arthur Rogers, D.S.O., and Edward Richard William Charles Carroll. The Queen has also approved of the retirement from the Service of the under-mentioned officers:—Surgeon-Captain Frederic Hewlett Burton-Brown, Bengal Establishment, and Surgeon-Lieutenant Alfred Moore, Madras Establishment. Surgeon-Colonel E. Townsend, A.M.S., is brought on the Administrative Medical Staff of the Army, vice Surgeon-Major-General C. McD. Cuffe, transferred to the Home establishment. The services of the under-mentioned officers are replaced at the disposal of the Government of India, Home Department:—Surgeon-Captain J. Mulvany and Surgeon-Captain E. H. Condon. The services of Surgeon-Lieutenant P. N. O'G. Lalor (Madras) are placed temporarily at the disposal of the Foreign Department for employment on plague duty. The services of Surgeon-Lieutenant F. Wall (Madras) are placed temporarily at the disposal of the Foreign Department for famine duty.

THE HEALTH OF THE SPANISH ARMY.

The medico-statistical report of the Spanish Army for the year 1894 has recently been made public in the *Revista de Sanidad Militar*, the contents being arranged under four separate headings as follows: (1) the Peninsula and its dependencies, (2) the island of Cuba, (3) the island of Puerto-Rico, and (4) the Philippine Islands. The average strength of the troops serving in the Peninsula and its dependencies, which comprise the posts of Ceuta and Melilla in Northern Africa, together with the Balearic and Canary Islands, was 87,585 of all arms, but exclusive of the gendarmerie which is not under the control of the War Minister. During the year 38,872 soldiers were admitted for treatment into military or general hospitals, and the ratio of sickness was consequently returned as only 443·8 per 1000 per annum; but this unusually low proportion is due to the fact that no account is taken of the numerous, more or less slight, cases which are disposed of in the regimental infirmaries. The deaths amounted to 737, or 8·41 per 1000—a rate considerably in excess of that of most of the other European armies. The compiler of the report is careful to point out that a great deal of the mortality is caused by the preventable diseases which usually attend on defective hygiene, and seizes the opportunity of strenuously urging upon the authorities the necessity for sanitary reform in barracks and hospitals. In support of his argument he cites the case of the British army, of which, in the course of a few years, the annual death-rate was brought down from 17·5 per 1000 to 4·7. In Cuba the average strength, including 4088 gendarmes, was only 19,040, but this, of course, was prior to the insurrection which during the last two years has been such a drain on the military resources of the kingdom. The admissions into hospital numbered 11,404, and were therefore at the rate of 598·9 per 1000; but here, too, unimportant cases find no entrance into the statistics. There were 385 deaths in the course of the twelvemonth, yielding a ratio of 20·22 per 1000 of strength; but this alarming mortality was mainly owing to yellow fever, which was responsible for upwards of two-thirds of the total loss. In other respects the Queen of the Antilles maintained her pristine reputation as one of the most salubrious spots inside the inter-tropical zone. It is true that paludism was rather prevalent, but judging by the mortality of 0·31 per 1000 the type of the disease must have been remarkably benign. In the neighbouring island of Puerto-Rico the general health of the garrison was not so good. Out of an average strength of 3438 men there were 3926 admissions to hospital and ninety-six deaths, the rates respectively being 1142 and 27·92 per 1000. As in Cuba yellow fever caused the greatest damage, the mortality in 171 cases having been equal to 39·2 per cent. Paludal and venereal affections were the chief forms of disease. The average strength of the troops in the Philippines was 20,189, but only 2404 were Europeans, the remainder being natives of the archipelago. The sick-rate for the two classes combined was 510 per 1000, but for the Europeans alone it was 1152 per 1000. On the other hand, the death rate in the case of the latter was 8·49, whereas for the natives it was 12·48.

CHOLERA IN INDIA.

India has been terribly visited of late, with plague, pestilence, and famine, followed by earthquake. The accounts of the epidemic of plague are, we are glad to say, satisfactory; the health of Bombay is now good, and continues to improve. We regret to notice, however, in the Indian papers received by the last mail, that cholera has made its appearance at several Indian stations. It should be borne in mind, however, that this is the season at which it frequently does so. The disease has broken out in the lines of the 19th Hussars at Secunderabad. Seven cases of cholera have occurred at the Fountain Hotel, Mahableshwur, four of which proved fatal. Latest advices from that station report that no fresh cases have occurred there. There were fifteen deaths at Bombay reported during the week ending June 1st, and the disease is stated to be prevalent in the districts surrounding Jubbulpore. Cholera has also broken out in an epidemic form in Belgaum and its vicinity, thirty cases having occurred in two or three days.

THE BOYLE SYSTEM OF VENTILATION FOR STEAMSHIPS.

This system, a descriptive pamphlet dealing with which we have received, has been severely and carefully tested for several years, and has been favourably reported on by naval and scientific authorities. It possesses double the ventilating power of previous forms of such apparatus, and these ventilators "have no moveable parts to get out of order." Messrs. Boyle have, it seems to us, arrived at a comparatively simple and economic solution of one of the most difficult problems in sanitation, and we look forward to the employment of it in our troop ships, or "hospital" ships when we get them.

Hosted by Google

The principles of ventilation are well known, but how to adopt these to climate, the speed of steamers, the limited space available, and such like contingencies are the desiderata. Again, when the medical aspect of the question is approached, and provision has to be made for sick and wounded persons, further difficulties have to be overcome. Messrs. Boyle have taken an initial step towards solving an important problem.

THE DIAMOND JUBILEE HONOURS.

The names of the following medical officers appear among the list of Honours bestowed on the occasion of the completion of the sixtieth year of Her Majesty's reign:—Inspector-General of Hospitals and Fleets, H. F. Norbury, C.B., to be K.C.B. (Military); Inspector-General of Hospitals and Fleets J. J. L. Donnet, to be K.C.B. (Military); Inspector-General of Hospitals and Fleets H. Macdonnel, R.N., to be C.B. (Military); Surgeon-General C. A. Gordon, C.B, Hon. Physician to the Queen, to be K.C.B. (Military); Surgeon-Major-General C. Sibthorpe, I.M.S., to be C.B. (Military); Brigade-Surgeon-Lieutenant-Colonel G. W. McNalty, to be C.B. (Military); Surgeon-Major-General J. Jameson, Director-General, A.M.S., to be C.B. (Civil); Deputy-Inspector-General of Hospitals and Fleets H. C. Woods, to be a Member of the Fourth Class Royal Victorian Order; Surgeon-Major-General Hooper, President of the Medical Board, India Office, to be C.S.I.; Surgeon-Major-General Cleghorn, Director-General of the Indian Medical Service, to be C.S.I.

"Audi alteram partem."

DRAFT BILL FOR THE REGISTRATION OF MIDWIFERY NURSES.

To the Editors of THE LANCET.

SIRS,—In your issue of June 19th, p. 1684, you kindly publish extracts from my above Draft Bill. Since sending it to you I have resolved to extend this Bill so as to include, not only midwifery, but also medical, surgical, and other nurses. I hope this will please all parties, and that we shall soon get rid of an important subject.

I now wish to ask through THE LANCET that the Secretary of each Medico-ethical Society, each Branch of the Brit. Med. Assoc., and each hospital committee and medical staff interested in this question shall now obtain a Copy of this Draft Bill and bring it before his members. I shall be glad to answer any questions. Copies of this Draft Bill may be obtained from my printers, Messrs. Hill and Co., 10, College-lane, Liverpool, at about the following prices, carriage paid: 25 copies, 5*s.*; 50 copies, 8*s.* 6*d.*; 100 copies, 12*s.*

May I at the same time request practitioners to send me a subscription to the Society, formed for the purpose of pushing this Bill through Parliament. Since 1890 I have expended out of my own pocket £373 13*s.* 8*d.* in opposing the five Midwives Bills. Since Feb. 10th, I have expended about £43. It will require a considerable sum—even to defray postage and printing—when I sent a copy of this draft Bill and a circular letter to all hospitals and Medical Societies, Colleges, Medical Schools, Universities, and Poor-law Guardians—i e., some 1684 Boards of Guardians, 385 Medical Societies, and 1506 Hospitals, or a total of *at least* 3575 penny stamps required. I am more than willing to give my best time, services, and money, and the services of those in my house, but I cannot finance work which directly concerns each practitioner.

I am, yours truly,

Liverpool, June 21st, 1897. R. R. RENTOUL.

"A METHOD OF UNITING THE DIVIDED INTESTINE."

To the Editors of THE LANCET.

SIRS,—Under the above heading the writer of a letter that appeared in THE LANCET of June 19th courteously acquits me of any want of originality. For this I thank him and beg to assure him that after a very careful search among all records and inquiries among many London surgeons I neither found nor heard of any article of his or of anybody else that described the operation I ventured to publish on May 22nd. Without a copy of the article in question it is impossible for me to know how much my operation resembles or differs from that of the American surgeon.

I am, Sirs, your obediently,

Harley-street, W., June 21st, 1897. G. LENTHAL CHEATLE.

*** The Society of Science, Letters, and Arts of London, to which Dr. Hartigan has sent his paper, no longer exists, and was, we are informed, a bogus institution.—ED. L.

"RESPIRATORY SYMPTOMS OF TOBACCO POISONING."

To the Editors of THE LANCET.

SIRS,—A paper by Dr. Morrow under the above heading has recently appeared.[1] I may be permitted to state that some years ago I forwarded to THE LANCET a brief remark upon a case of gasping respiration, in which note the exhibition of the symptom, being commensurate in degree with the extent of tobacco consumption, was attributed solely to this habit, and appeared to be a variety of Cheyne-Stokes respiration (although somewhat departing from the normal type of such), certainly as being some kindred theme from the medullary gamut of lung rhythm. One point in my case was that the distressing symptom was confined to the first hours of bed and was peculiar to the horizontal position. Dr. George Herschell, a few years ago, published a case of laryngeal spasm the cause of which, in part, he referred to tobacco—a point of some interest in this *rapport*. In conclusion, seeing that tobacco may cause perversion of central function, as in Dr. Morrow's thesis, and since it may bring about change of nerve structure also, as in retinal atrophy, it might be worth while to consider and to search out how far this universally distributed luxury be a contributory factor in either the genesis or the development of tabes, general paralysis, indeed, in all diseases of nerve, central or peripheral, functional or structural, cerebral or spinal, sympathetic, vasomotor or trophic.—I am, Sirs, yours faithfully,

G. HASSALL HUNTLEY.

Lees-road, Oldham, June 7th, 1897.

THE PLAGUE IN BOMBAY.

(FROM A CORRESPONDENT.)

II.

MY communication which appeared in THE LANCET of March 27th dealt with some of the physical and social aspects of the city of Bombay from the point of view of a sanitary engineer, but no true appreciation of its present state, and the causes which led to it, can be arrived at without an outline of the governing body which controls the finances and the executive officers of the municipality. The Bombay municipality is the outcome of an experiment on a very large scale made twenty-five years ago by the Indian Government with a view to teach the Indians the art of managing their own local affairs. Based, of necessity, very largely on English models, its defects were soon apparent, and the assumption that the whole city could produce seventy-two representatives, all of them both able and willing to serve the best interests of the community gratuitously, was found to be erroneous. Bombay has never yet sent a fourth of that number of good men to the municipal council at any one time.

Among the seventy-two representatives sixteen are elected by the Bench of Justices, two by the Chamber of Commerce, two by the University, and sixteen by the Government The corporation elects its own President, and from its members the standing committee of twelve is elected, eight of whom are nominated by the corporation and four by Government. They are paid for their attendance. In addition

[1] Brit. Med. Jour., June 5th, 1897.

Hosted by Google

to the usual executive officers and office staff, the Bombay municipality has a municipal commissioner, who in recent cases has been a collector and a magistrate from the Civil Service, but there is no law requiring him to belong to any branch of the Government service. He is appointed by the Governor of Bombay, and is the paid servant of the corporation, who have powers to dismiss him. His actual position has no parallel in any other corporate body. The entire executive power rests in the Commissioner. He may prescribe the duties of, and exercise supervision and control over, the acts and proceedings of the health officer, the executive engineer, the assessor, and their several subordinates, and is presumed to be capable of dealing with everything relating to these departments. The situation was none of his making, the pay is good, and under such circumstances it is not surprising if some of the Commissioners entered so far into the spirit of their office as to nullify by interference the responsibility of the executive officers. About a year ago the corporation voted a sum of Rs. 7000 for printing a report on drainage drawn up by the Commissioner for their instruction. It was the same official who had already opposed the making of certain experiments to provide scientific data that were wanting for the proper ventilation of the sewers. It is needless to say that a subject that has not yet been completely developed by the best engineers in India could gain nothing at the hands of an amateur without practical experience. The tendency of the Commissioner is naturally to guide and direct the corporation, and that of the corporation to have its own way. The latter has also strong parliamentary instincts and an innate taste for diplomacy, so the Commissioner's party and the "opposition" form the chief divisions of the corporation. No standard of education is required of members of the corporation. Their elections recall the methods in vogue fifty years ago in England, and many of them, after years of service, have only an elementary knowlege of the Municipal Act which forms their constitution. There are among their number a few men of the best type, whose unselfishness and singleness of purpose would be an honour to any municipal body, but their work is rendered doubly onerous by the opposition of their colleagues, whose salient points are the making of long and inconsequent speeches and the faculty of combining for voting purposes. Many of the members consider they have a right to recommend friends and relatives to subordinate positions in the municipal service, leaving the heads of departments little or no choice in the matter; others resent as an affront notices served upon them by the Health Department for breaches of conservancy rules. The executive officers are elected by the corporation.

The revenue administered by the municipality amounts to Rs.6,300,000 per annum, and the population last year was 823,000, but after an existence of a quarter of a century the corporation generally does not understand its duties, and the present condition of the city is directly traceable to its administration. Shortly before the outbreak of the plague occurred the steadily increasing mortality in the city attracted the attention of the Grant College Medical Society, which, after three full meetings, passed three important resolutions which attributed the rise in mortality to the increasing foulness within and around the dwellings. The society made a careful investigation of the matter, which it presented in the form of a report to the corporation. Instead of promptly recognising the great value of this timely communication on the insanitary state of Bombay the leaders in talk derided the report and jeered at the society that sent it, and the corporation refused to allow it to be read. The epidemic that followed is now a matter of history.

When it was authoritatively established that plague was raging in the city a member of the corporation proposed to his colleagues the establishment of a vigilance committee, with full powers to incur any necessary expenditure for stamping out the disease, which was then confined to one or two districts only. The idea conveyed in the proposal was to establish a permanent Plague Committee, but the corporation agreed not to touch the business, but to place the whole responsibility on Government and hold Government responsible for everything, including, of course, the expense. Government, as has been seen, accepted the position, at least, as far as administration was concerned.

The limited area of the city and its commercial prosperity have resulted in a constant dearth of houses and an increase of rents unknown in the interior. After careful inquiry I learn that the net return on various classes of house property, including ground rent per annum, is as follows:—

	Per cent.
Good chawls or dwellings for the labouring classes	9·75
Bad chawls	15·2
Shops in the fort and city	14·7 to 39·9
Tenement houses	8·82
Offices	8·82
Bungalows with gardens in the suburbs ...	4·87

Many of the most insanitary habitations which have been destroyed by the Plague Committee as unfit for human habitation belonged to some of the wealthiest and most prominent citizens or to members of the corporation. Chawl property, consisting of buildings of from one to three storeys, constitutes two-thirds of the dwellings in Bombay. It was the supineness of the municipality in the early weeks of the plague that brought about the interference of the Government and the appointment of the Plague Committee under General Gatacre, which practically superseded the municipality in all matters dealing with the epidemic. The most powerful faction in the corporation is, of course, that of the house proprietors, who, at the beginning of this year, numbered thirty-one, or 43 per cent. of the whole. Of the twenty-six remaining Indian members it is reasonable to suppose that a certain number, although not owners of property, will vote for various reasons, not all connected with the public interest, on the side of the house proprietor on all questions affecting his interests. The landlords form a body which has the greatest personal interests at stake in the corporation, and, whatever they may have done for the rest of the citizens, they have given the strictest attention to their own affairs, and in this way the worst vices of structural arrangement of dwellings have been maintained, conservancy rules and regulations have been set at nought, and the water-supply has been misused until it is recognised as an important factor in contributing to the death-rate of the city. Bombay possesses one of the finest water-supplies in the world. It is derived from storage reservoirs among the hills to the north and north-east of the city, and it arrives by gravity. The three reservoirs—Vehar, Tulsi, and Tausa—were constructed in succession to meet the growing consumption of the city, which now receives about 42 gallons per head per day of water collected during the five months of rain and stored during the seven dry months. The actual consumption of water by Indian populations has been carefully noted by many observers—that is to say, the amount actually used by the people. What they will waste, if unchecked, is limited only by their facilities. In Cawnpore the maximum average consumption per head per day was 7½ gallons, including that used for flushing the street gutters before the construction of the waterworks. At that time all water for domestic use had to be drawn from wells having a depth of from thirty-five to fifty-five feet. After the waterworks had been in use for three years the average daily consumption of water from the pipes was 5·35 gallons for all purposes. The majority of the Indian people wear very little clothing. Their bedding is scanty, and they have no table linen. Their industries are established near rivers, wells, or tanks, and do not yet depend on water-works supplies. From information recently obtained the consumption of pipe water per head per day in Agra is 6·44 gallons; in Ahmedabad, 10·0; Delhi, 6·0; Simla, 8 0; Lahore, 7·29; Hyderabad (Sind), 9·6; Colombo, 19·0; Quetta, 20 0; Ajmere, 5 0; Peshawar, 5·83; Madras, 16·0; Karachi, 23·8; and Bandra, 2·12 gallons. Madras and Karachi are sewered, and have sewage farms which practically purchase the sewage effluents. Bandra has to pay Bombay 12 annas per 1000 gallons of water supplied from the waterworks of the latter town, and the consumption, as shown above, averages only 2 12 gallons per head per day. The Bombay supply, averaging 42 gallons per head per day, indicates unchecked waste on an enormous scale. This waste has been the subject of annual protests on the part of the health officer, who said that the soil had become waterlogged, that 4,000,000 gallons of the daily supply were not accounted for at the sewer outfall, and that the rate of mortality was steadily rising. Every known method of check upon waste has been determinedly opposed by the corporation, who, so long as they paid their rates by assessment, could waste water in gardens and stables without check. The result is that the cost of waterworks has been increased

Hosted by Google

until the water has to be charged when sold by meter at the rate of 12 annas per 1000 gallons, while water at Cawnpore, Agra, Delhi, and Lucknow, which is pumped from rivers and again pumped into the mains, is sold at 4 annas per 1000 gallons. If waste were rigidly checked and the surplus water were sold for irrigation it would be possible to lower the price of water in Bombay. In 67 large towns in Europe, all of them sewered, the average daily consumption of water per head is 20·1 gallons, and they have among them 83,988 water meters. Two years ago the filter beds serving Malabar Hill, the most fashionable suburb of Bombay, were found to be in a horrible condition from neglect. The reservoir water was fouled in its passage through them, and the water engineer, who was absent on leave, was severely censured by the corporation. On his return he produced official correspondence proving that the corporation had refused to sanction the expenditure for cleansing the filters. This gentleman took the first opportunity to find another place.

Interfering with the duties and responsibilities of its executive officers is an incorrigible fault of the Bombay corporation. The construction of buildings by unqualified persons has led to frequent and fatal accidents, for every Indian who can pay for a new house, or even an alteration, considers himself qualified to design it with the aid of a foreman builder, whose advice is, of course, gratis. House property is bought without any proper survey, no questions are asked provided the price is low enough, and storeys are added regardless of the state of the lower part of a building. This went on for years without any movement on the part of the corporation either to check builders or to provide a salvage corps to rescue the victims. This scandal might have continued had not the daily papers entered a vigorous protest against the municipality on an occasion when their engineer stopped the search in the *débris* of a fallen house for bodies, dead or alive, at nightfall, on the pretext that it was dangerous. The defective constitution of the corporation of Bombay seems to have penetrated all its committees, which, as their numbers increase, seem to lose all individual responsibility. Instead of thrashing out the question before them on its merits these committees divide deliberately into factions and contend for the orator who is most likely to influence votes when the time comes for making resolutions. This taste for what is supposed to be eloquence is a very common vice among public men in India. It has had the effect of keeping capable European business men out of the municipal council. They look on it as a waste of time. The Europeans who at present serve as councillors are mostly nominees of the Government or of certain public institutions.

The recent drastic treatment of the Calcutta corporation by the Lieutenant-Governor of Bengal has led the public to indulge in the hope that in view of recent events and of its past history important changes may be introduced at an early date into the constitution of the Bombay municipality. There is another corporation in Bombay from which many useful lessons might be derived. The Bombay Port Trust is administered by a board of thirteen trustees, six of whom are elected by the Chamber of Commerce and seven by the Government. The board administers an annual revenue of about Rs. 5,000,000, and its meetings are remarkable for an absence of speechifying and a capacity for getting through work. Such a body could not be brought together in India by any popular election. The experience of a quarter of a century of municipal administration in Bombay has proved that no body composed principally of Indians can be counted on to initiate and apply vigorously the regulations that are necessary for the well-being of a densely crowded city. Their feelings are on the side of their friends and constituents, and the latter are ever ready to claim the ægis of religious custom—and consequently toleration—for every insanitary habit. This was the plea that was brought forward against the closing of a graveyard in the heart of the town in which victims of the plague were being buried a few weeks ago. Religious custom also required that about twenty-eight hospitals should be constructed in and around Bombay to receive plague patients of the various communities, many of whom would have been ceremonially defiled by being sick or dying in the same room with people of another caste. Each of these hospitals had its own staff even if it contained only one patient. Caste prejudice enters largely into the details of sanitary engineering. The sweeper, who removes nightsoil from dwellings, is looked down on by nearly every community. Neither Parsee, Hindu, nor Muslim will allow him to enter his house. The domestic latrines are so arranged that the sweeper can only approach them from without. They are consequently never properly cleansed, and if any member of the family should contract any disease of a contagious character the latrine plays an important part in the spread of the disease.

Complete freedom of movement without passports, and the enjoyment of his "customs," good and bad, almost without restriction, have combined to render the Indian averse to all change and impatient under new conditions. He does not suspect that in some other countries an epidemic of plague would have brought the city under martial law, with all its summary methods of procedure.

The Bombay municipality as at present constituted is quite unfit to manage the affairs of the city. It has failed signally in the management of the water-supply, the drainage, and the conservancy of the municipal area. The commissioner has too much power and too little—too much for his technical knowledge and too little for the knowledge of public business he brings to his task. He arrives profoundly ignorant of many things he is called upon to adjudicate, and at the end of a five years' apprenticeship he is liable to be called to other duties when he is of most use to the city, to give place to another man as little *au fait* as he was at first in the work.

As the need of good government increases with the population—which cannot spread freely—the present time offers an excellent occasion for a complete reform of the municipal constitution of Bombay. It is no question of expelling the Indian, for without his aid local self-government could not succeed completely. Means must be found to attract the best men—native and foreign—to keep down the dangerous element to a minimum and to increase individual responsibility all round. There is no lack of good material for a governing body in Bombay. What is wanted is the means to get it together.

Bombay, May 15th, 1897.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Overcrowding in Red Bank.

THOUGH much has been, and is still being done, in Manchester to prevent overcrowding and to open out the slums of the city, such cases as the following show that the work is still far from completion. An inquest was held at the City Coroner's Court on Monday week on the bodies of the twin children of a Polish Jewess living in a court off Red Bank. These infants were said to have been healthy at birth, three weeks before. Their bodies were in a dirty, neglected condition, and "bore a number of sores." One, a boy, weighed 4 lb. 1 oz., and the other, a girl, 3½ lb., instead of about 9 lb. each. The boy died from cerebral hæmorrhage, and the girl "from lack of food." The woman had been deserted by her husband, but had for some time been living with another man, a compatriot, and four children, in a room 9 ft. by 6 ft. This district is largely occupied by the poorest of poor Jews, most of them foreigners, many, like the mother of these children, unable to speak English, living sometimes in squalid abundance, at others in a state of semi-starvation, but almost invariably with persons and dwellings disgustingly filthy. And yet, as Dr. Niven tells us, the death-rate among the Jews in Manchester, is remarkably low.

The City Industrial Schools.

The fiftieth annual report of the Manchester Certified Industrial Schools has just been issued, and shows work valuable to the community as well as to those rescued from lives of wretchedness and crime. The admissions during the year have been 145. At the school at Ardwick there are 51 boys, and 73 at the Barnes Home a few miles out of Manchester, while at Sale there are 21 girls. Of these, 5 boys were found begging; 71 boys and 12 girls were found wandering without proper home or guardianship; 26 boys and 3 girls were charged with theft or living with reputed thieves; 12 boys and 3 girls were sent to the schools as incorrigible; 8 boys and 1 girl were charged under the Elementary Education Act: and 2 boys and 2 girls were found living in houses of ill-fame. In the three schools there

Hosted by Google

are now 573 boys and girls, 100 of the latter being at Sale. During the past four years 485 boys have been discharged, and 398 are stated to be doing well. Coming as they do in most cases from the lowest stratum of the "residuum," this is perhaps as good a record as could be looked for.

Workhouse Dietary.

Attempts have been made from time to time by the guardians of the Manchester Unions to improve the dietary and avoid the waste complained of under the present system. Their well-meant efforts, however, have always been defeated by the Local Government Board, as they would have disturbed the rigid uniformity now in favour, which, though bad for the ratepayers and not beneficial to the inmates of the workhouses, gives perhaps less trouble to clerks and officials than would follow the change. At Blackburn on Saturday week the guardians discussed this question. One said there could be no waste when "three meals daily only cost fourpence per head." Another said that he and other members of the Farm Committee "had seen five 18-gallon barrels of waste food taken to the swill-tub." A lady guardian said the root of the matter lay in a fixed dietary scale, and that as long as it was imposed "there was bound to be waste." This opinion is widespread among those who see the practical working of the present system, but as it is stereotyped there is no doubt great reluctance felt in breaking it up, even though its use is attended by manifest evils. Fourpence does not seem an extravagant sum for three meals, and the workhouse inmates must surely have their food presented in a very unattractive form if so much goes to the "swill-tub."

The Owens College.

Those interested in the successful progress of the Owens College, are naturally much gratified by the report of the Treasury Commission of Inspection of the University Colleges in Great Britain. The work done at Owens College is reported on in detail with a view to the guidance of the Lords of the Treasury, who are to have £25,000 a year at their disposal for grants, instead of £15,000. The commissioners recommend that the proposed maximum sum of £3000 be given to the Owens College, and, "as their proposed division leaves a balance of £500, they suggest that this sum also should go to the Owens College, in recognition of its pre-eminence. The Lords of the Treasury agree to this."

Explosion at a Chemical Manufactory.

On the 15th inst. a violent explosion, causing the loss of two lives, took place in Manchester at the works of a manufacturing chemist and tar and naphtha distiller. A still, 14 ft. deep and 12 ft. in diameter, containing 30 tons of oil, was blown bodily from its setting of brickwork, and carried over a high wall to the opposite side of an adjoining street. There was a tremendous report, and flames were seen rising from a portion of the works. The burning oil was scattered in all directions, and some of it fell on the vats and tanks that are distributed about the works, containing oil and pitch, setting them on fire. The bodies of the two men killed were so blackened and disfigured as to be almost unrecognisable. They must have been killed instantaneously. The accident is said to have been caused by the stoppage of a condenser in the still. Several other men had narrow escapes. There was abundant help from the fire brigade and private appliances, and the fire was extinguished in about half an hour. No doubt careful precautions against fire are the rule, and with such inflammable materials "distributed about the works"—according to the report given in the *Manchester Guardian*—they are not unnecessary.

Manchester Therapeutical Society.

On Wednesday, June 16th, the first general meeting of the above society was held at the Owens College. Professor Leech delivered an address upon the objects of the society, the considerations which had led to its formation, and the lines of future work. A number of new drugs and preparations were exhibited. Rules for the management of the society were adopted and the following officers elected for the session 1897-98. President: Professor D. J. Leech. Vice-Presidents: Professor Dixon Mann and Professor Delépine. Hon. Treasurer: Dr. R. T. Williamson. Hon. Secretary: Dr. R. B. Wild. Committee: Dr. Bury, Dr. Coutts, Dr. Hopkinson, Dr. Kelynack, Dr. Steell, and Dr. Wilkinson.

June 22nd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary, Newcastle.

MR. RILEY LORD has accomplished his object and raised £100,000 for the rebuilding of the Royal Infirmary. For years the necessity of rebuilding the infirmary has been apparent and talked of, but nothing was done. It is entirely due to the energy and perseverance of Mr. Riley Lord, the ex-mayor, that funds have been raised enabling the committee to carry out their long-cherished object. It will require a larger sum than that already raised to build a new infirmary, but it will be forthcoming in due time. The raising of £100,000 to build a new infirmary in commemoration of the Queen's long reign is perhaps the largest effort which has been accomplished in England out of London.

Drunk or Ill?

One day last week a young gentleman was arrested in one of the principal streets of Newcastle-upon-Tyne and locked up on the charge of being drunk and incapable. At the station he requested to see a medical man, but this was refused. After having his valuables taken from him and being confined for some hours in a police-cell he was allowed to go home. On Friday last the case was investigated by the magistrates, when an inspector, three sergeants, and four privates swore the youth was drunk when arrested. On the other hand, it was sworn that the accused was a life-long teetotaler, that he had never tasted alcohol in his life, and that he was subject to fits. The magistrates dismissed the case and censured the police. This is a very significant case. That a policeman should make a mistake where the question of illness or drunkenness arises is not to be wondered at; but that eight men, some of them experienced policemen, should all swear positively that a sick man was drunk is, to say the least of it, very disquieting. That the accused should not have been allowed to see his own medical man as he wished is simply a scandal of the gravest kind. We often hear of the uncorroborated evidence of a policeman, but in this case no fewer than seven corroborated, and yet their evidence proved to be incorrect.

Newcastle-upon-Tyne, June 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons of Edinburgh: The Queen's Diamond Jubilee.

IN commemoration of the Queen's Diamond Jubilee a reception was held by the Royal College of Surgeons of Edinburgh on the afternoon of the 22nd inst., to which the members of the medical profession in Edinburgh and the heads of public bodies were invited. Refreshments were served in the hall. The conservator, Mr. Cathcart, and other Fellows of the College, attended in the museum to explain the specimens, and various demonstrations of the Roentgen rays were given. In the library were placed a series of photographs of cases which had been elucidated by the rays in the Edinburgh Royal Infirmary. In one of the examination rooms the process of using the rays was shown by Dr. Dawson Turner, medical electrician to the Edinburgh Royal Infirmary, and in another room lantern views of cases elucidated by the rays were shown, with explanations by Dr. Scot Skirving. The guests, about 600 in number, included ladies, and were received by the president, Emeritus Professor Struthers, and the council. The College, the most ancient of all the medical corporations in the United Kingdom, is to be congratulated on its action in thus gathering under its roof the medical profession of the city on the historic occasion of the completion of the sixtieth year of Her Majesty's reign, a period during which such great progress has been made in medical science.

Glasgow District Asylum at Gartloch.

This institution has now been completed and declared open. It consists of two parts, asylum and hospital. The former is for chronic and incurable patients and contains 380 beds. It consists of four large blocks, three storeys in height, with boot and bath rooms attached. These blocks are connected with the administrative and official departments by long corridors, under which are subways where are

Hosted by Google

found the heating pipes, water-supply pipes, and electric light cables. The hospital is a separate building, and has a separate kitchen and dining hall, while for asylum and hospital there is a common recreation room. It contains 150 beds and is principally of one storey. In it are the admission wards, wards for the treatment of intercurrent bodily diseases in the insane, wards for old and feeble cases, and infectious blocks. The whole buildings have been suitably furnished and are well adapted for their purpose. The lighting throughout is electric, the heating is by radiators, and the water-supply is from the Glasgow mains. The asylum is situated about seven miles from Glasgow, on an estate of 400 acres, and is built in the Francois Premier style of architecture from the plans of Messrs. Thomson and Sandilands, of Glasgow. The total cost will not fall much short of £200,000. The physician superintendent is Dr. L. R. Oswald.

Glasgow University.

The following gentlemen are understood to be candidates for the chair of Materia Medica and Therapeutics vacant by the death of Professor Charteris—viz., Dr. J. W. Allan, assistant physician, Royal Infirmary; Dr. C. O. Hawthorne, lecturer on Materia Medica in the University, and assistant physician, Western Infirmary; Dr. William MacLennan, University assistant to the late Professor Charteris; and Dr. Alex. Napier, physician to the Victoria Infirmary, and formerly Professor of Materia Medica in Anderson's College Medical School.

Consumption Hospitals for Scotland.

The Medical Board of Advisers has at last issued a statement in support of Mr. Quarrier's appeal for funds to carry out his scheme. The committee draws attention to the fact that some 7000 persons die annually in Scotland from consumption of the lungs, 1400 of these being registered in Glasgow. It is then stated that the disease undoubtedly spreads by infection, more especially in the unwholesome atmosphere of the crowded houses of the poor, and that there is every reason to believe that many cases are curable if treated in the early stage. The committee gives a decided opinion in favour of the situation and arrangement and equipment of the hospital already erected, and recommends to the public the scheme in which it is contemplated to erect six other hospitals at a further expense of £40,000. The committee also express their approval of the arrangements which Mr. Quarrier is making for the management of the hospital and for the medical supervision of the patients. It is so far satisfactory to know that the committee is actually in operation, and no one can doubt their interest both in the public welfare and the advancement of medical science. Their statement is not, however, beyond criticism. Mr. Quarrier's published scheme included the erection of a dispensary in Glasgow at a cost of £3000. Do the committee approve of this or do they not? In their report they say: "It will be necessary to provide in Glasgow a central office where patients recommended may be examined," but this is a very different thing from Mr. Quarrier's plan. Again, it would appear from the committee's report that the arrangements for the medical supervision of patients are entirely in Mr. Quarrier's hands. His plans so far are approved by the committee, but what guarantee is there that those plans will be adhered to, or that, as further arrangements are needed, these will meet the committee's views; and if further arrangements are unsatisfactory, what will happen? Apparently, the committee has no authority or power in the matter. It may every now and then have the opportunity of expressing approval of what has been done, but its existence is purely *ex gratiâ*. There is no need to impugn Mr. Quarrier's disinterestedness or good faith. The question is one of public policy, and a policy which advocates the raising of a large sum of money for the erection of hospitals for the phthisical, the administrative and medical management of which are to be practically at the pleasure of one man, is one which lends itself to comment. Even supposing that Mr. Quarrier is likely always to pursue an enlightened policy and to defer to his board of advisers, what guarantee can be given for his successor? If, when all the money is raised, the board of advisers find they are no longer heeded, surely they ought not to be much surprised. It may fairly be contended that their present position has this radical weakness. They bear responsibility—for undoubtedly subscriptions will be given under the influence of their names—but the responsibility is not associated with authority. Such a severance is most improper, and means at least the possibility of misunderstandings and of disaster.

Congress of Sanitary Inspectors Association of Scotland.

The annual congress of this association took place in the town-hall, Aberdeen, on June 18th, under the presidency of Mr. K. Cameron, chief sanitary inspector of the city of Aberdeen. About sixty delegates, representing all parts of Scotland, attended. The most interesting papers read were: (1) by Mr. W. Mackenzie, county sanitary inspector of Ross and Cromarty, entitled Notes on the Sanitary Conditions existing in the Outer Hebrides, as exemplified in Lewis (which was followed by a resolution calling the attention of the Secretary for Scotland to the public scandal arising from the present miserable housing of the people in the Outer Hebrides and Western Islands), and (2) by Mr. A. T. Gordon Beveridge, M.B., C.M. Aberd., a member of the Aberdeen town council, on the Housing of the Working Classes. The members were afterwards treated by the town council to a drive round the city and suburbs and entertained in the evening to dinner in the Grand Hotel, Dr. A. T. G. Beveridge presiding.

Hospital Saturday in Aberdeen.

The demonstration arranged by the amalgamated friendly societies took place on June 18th. The weather was favourable and the procession through the streets was very successful. The attendance at the athletic games, &c., in Duthie Park, however, amounted only to 10,000 persons, but it is hoped that the total free proceeds from all sources, including subscriptions, will be in accordance with expectation.

June 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

A GREAT improvement in the health statistics of Dublin was recorded by the Registrar-General's report for the week ending June 12th. Notwithstanding that the epidemic of children's diseases—measles, scarlet fever, and whooping-cough—has not entirely disappeared, the number of deaths registered was below the decennial average. At the meeting of the Public Health Committee on Tuesday, June 15th, Sir Charles Cameron reported the death-rate to be 23·4 per 1000 persons living, the mean rate being 25·7. A novel feature in this report is a sort of epitome of the sanitary work performed during the week. From the latter it appears that 987 houses, 5108 rooms, 65 slaughter-houses, 42 dairy-yards, and 22 nightly lodging-houses were officially inspected. The registrar of Cork-street Fever Hospital, at the last meeting of the Managing Committee, reported a decline in the epidemic of measles. Referring to diphtheria, he remarked that this disease, hitherto sporadic, was showing evident tendencies to assume an epidemic character. The use of antitoxin in early cases was reported as having proved very satisfactory. The conference recently held in the Public Health Buildings of representative citizens of Dublin, to consider the question of providing cheap and healthy dwellings for the very poor, was entirely successful. The Right Hon. Joseph Meade, who presided, made some valuable practical suggestions, while Mr. Adam Findlater in his speech remarked that the mortality during the early months of this year was terribly high, the deaths not being confined to one class, but having spread from the slums to the wealthier portions of the city. An influential committee was appointed to carry out the object of the conference.

Jubilee Honours to Medical Men in Ireland.

His Excellency the Lord-Lieutenant has intimated that, with the approval of Her Majesty, the honour of knighthood will be conferred on Dr. George Duffey, the President of the Royal College of Physicians of Ireland, and on Mr. William Thomson, the President of the Royal College of Surgeons in Ireland.

The Richmond District Lunatic Asylum.

At the fortnightly meeting of governors, which took place on June 15th, Mr. Conolly Norman, the resident medical superintendent, reported that there were now on the asylum books a total of 1812 patients, being 712 above the original nominal limits of legitimate accommodation. He mentioned

Hosted by Google

that since the last board meeting three female inmates had been attacked with beri-beri.

The Accommodation in the Belfast Police Cells.

At an inquest held recently in Belfast in reference to the death of a woman which took place in the Union Infirmary on June 12th, some interesting points were brought out in evidence in reference to the prisoners' cells at the Central Police Office. It would appear that the woman was arrested for drunkenness on June 5th and taken to the police office, whence on the next morning she was removed to the Union Infirmary, where she died six days later from pneumonia. No blame was attached to the medical man or to the police, but it came out in the inquiry, from police evidence, that the accommodation in the cells is the same now as it was thirty years ago, although Belfast has since trebled its size. Again, it seems that 10,000 persons pass through the hands of the police at the central office each year, and it would seem that, owing to the very limited accommodation, there is hardly sufficient opportunity for exercising discretion in reference to the treatment of special cases. There would appear to be no special room set apart for the watching of cases where perhaps, in addition to the effect of drink, there may be also surgical or medical complications. There are no female attendants for female patients, neither are there restoratives ready at hand nor beds available for prisoners taken suddenly ill. The jury found that the woman died from pneumonia, and approved of the action of the medical man and police, but added the following riders to their verdict: "(1) That the cells condemned by the corporation themselves should be rebuilt immediately out of the money already voted for that purpose twelve months ago; (2) that female warders should be appointed to relieve the police from personal attendance on female prisoners; (3) that simple restoratives should be available in the cells in cases of extremity; and (4) that proper beds in proper apartments be provided for such cases as that before them."

The Royal Victoria Hospital, Belfast.

The scheme which was started last November, of the people of Belfast honouring the Queen in her Jubilee year by raising £100,000 to build a new hospital, is, I am most gratified to announce, a complete success, as the list of subscribers published this Jubilee day (June 22nd) shows that the whole sum originally aimed at—£100,000—has been raised and additional sums are still coming in. Through the exertions of the Lord Mayor (Mr. Pirrie) the Queen has graciously consented, through the Home Secretary, to allow this new hospital to be called the Royal Victoria Hospital. The greatest praise is due to the Lady Mayoress, to whose constant energy, tact, and popularity the success of this hospital scheme is almost entirely due. The new hospital, built on modern plans, will unquestionably be an immense gain, not only to the city of Belfast, the population of which is now 300,000, but also to the flourishing medical school which it will tend greatly to strengthen on the clinical side.

June 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Rabies and the Academy of Medicine.

AT the Academy of Medicine a discussion has just arisen which is most likely only the beginning of an argumentative war as to the Pasteur Institute and the value of the anti-rabic inoculations. These latter have always had bitter enemies in France, and the communication which M. Rendu has just made to the Academy has given them new courage. M. Rendu reported a case of acute ascending paralysis brought on by the anti-rabic inoculations. The patient was a post-mortem room porter at a hospital, who in the course of examining the body of a man dead from acute rabies pricked his finger as he was cutting into the pancreas. Although the wound was carefully washed with an antiseptic solution he betook himself to the Pasteur Institute, and, starting on March 22nd, underwent the regular course of anti-rabic treatment. Quite suddenly on April 1st he developed rigors and fever, which grew worse on the following day. The patient took to his bed, and the gradual progress of the disease, accompanied by the most alarming symptoms, was observed, paraplegia of first the lower and then the upper limbs, paralysis of the sphincter, vomiting, distress, dyspnœa, tachycardia, &c., but with only a slight rise of temperature. Nevertheless, the injections were continued in doses of 2 c.c. per diem and the patient was cupped and treated with antipyrin. On the seventh day after the onset of the symptoms a marked improvement set in, and he was completely restored to health in three weeks' time. The patient was sent for a month to the country, and is at present engaged in his work in the theatre. M. Rendu does not consider this a spontaneous case of paralytic rabies: the period of incubation was too short; the clinical course did not resemble that of the disease in question; there were no other symptoms of rabies; and, besides, paralytic rabies is always fatal. M. Rendu rejects equally the theory of an acute ascending paralysis of toxic orgin. For if the toxins had been introduced by the inoculations it is impossible to explain how the patient got well in the face of the continuance of these same inoculations. M. Rendu can only see one explanation, and that is that the patient, placed as he was by the exigencies of his occupation in very infected surroundings, was in a morbid state, which made him specially receptive. In this state the anti-rabic toxins might have determined an attack of myelitis. M. Roux, the director of the Pasteur Institute, replied to M. Rendu. For himself he did not consider the anti-rabic emulsions injected at the beginning of the treatment were capable of bringing about nervous crises, for they were always tested on very sensitive animals. He had seen two cases of paraplegia similar to that reported by M. Rendu, and he was certain that the anti-rabic treatment had nothing to do with them. These two cases, the only ones noted at the Institute since its foundation out of 19,000 cases treated, permitted him to affirm that there was no relation of cause and effect between the anti-rabic inoculations and these cases of paraplegia. Statistics like those of the Institute proved up to the hilt, he added, the absolute harmlessness of the anti-rabic treatment. M. Laveran had seen some years ago a case similar. It occurred in the Val-de-Grâce, and was considered an abortive form of rabies. Paralytic attacks of this kind did not always terminate in death. M. Grancher remarked that at the commencement of this system of treatment at the Institute a number of cases of so-called paralytic rabies were observed which had no canine origin. Generally they had to do with hysteria or alcoholism. M. Rendu's patient might be the subject of some form of neurosis or intoxication. M. Brouardel said that he had never yet seen rabies transmitted from man to man by inoculation. On the other hand, it is not uncommon for an ascending myelitis to follow a post-mortem prick. The case of M. Rendu should be classed as pseudo-rabies. Paralytic rabies does occur in men, and Morgagni was the first to describe it. M. Dumont Pallier remarked that the discussion which had arisen out of the communication of M. Rendu was of the highest importance. Could the anti-rabic treatment after the Pasteur method be held guilty or no? This question must be cleared up, and he proposed to submit it to the Academy

The Microbe of Seborrhœa.

The excitement caused by the discovery of M. Sabouraud of the microbe of seborrhœa, its identification with that found in cases of falling of the hair, its *rôle* in the etiology of baldness, and finally the researches by which M. Sabouraud was enabled to produce baldness in a rabbit by injecting a culture of his microbe, was so great among dermatologists that it was unanimously decided to hold a special sitting at an interval of a month from M. Sabouraud's first communication to discuss the matter. This meeting has just been held and was somewhat stormy. M. Brocq remarked that the seat of the bacillus was not in the hair follicle, and that its action on the skin could not be explained. M. Sabouraud had said it was from a toxin, but from his experiments the toxin apparently worked at a distance from the hair follicles at least in the rabbit, while in man it acted locally if the bacillus was always the cause of the seborrhœa and the baldness. All clinicians knew that temperament played an important part in the matter of seborrhœa and alopecia. As regards the latter, the arthritic diathesis had to be considered; as regards the former, the lymphatic. In a non-arthritic person baldness never occurred, not even when abundant seborrhœa was present. Clinically, we must not confound seborrhœa and baldness. If baldness was always due to a microbe it should be easily contagious, and it was not so except as accessory to some other disease. M. Jacquet considered

Hosted by Google

that the rabbit was not a good subject in this matter, for baldness can be easily produced in this animal by the simple application of bisulphate of calcium. M. Darier stated the histological analogies between seborrhœa and baldness, but as the results on the clinical side were different from those of the laboratories it was impossible without further information to identify the two lesions. M. Barbe said that many seborrhœic patients never had the least amount of falling off of the hair. Other speakers followed, all more or less in opposition. M. Sabouraud, in reply, reminded members that when Pasteur laid the results of his fermentation studies before the Academy everyone was against him. After thirty years, he added, all the discourses of the opposition are not worth one single Pasteur flask. So it would be with his researches—truth would come out, not by mere discourses, but by experience and experiments in the Pasteur way.

The Town Ambulances.

M. Paul Strauss, President of the Commission on Urban Ambulances, has just presented his report to the Municipal Council. The report recommends that every ambulance should be accompanied by a medical man and a hospital orderly. To carry out this scheme there must be four surgeons for every station and three orderlies for every ambulance. The latter will be drawn by two horses. Sixty "avertisseurs d'accidents" will be stationed in the streets, so as to be at the service of the public, in situations where they are considered most needed. The prefect of police will be invited to warn the ambulance stations whenever a fire breaks out. Before organising this system for the entire town the Commission have decided to make a practical trial at the Hospital of St. Louis. It was at this hospital that the experiments in First Aid were tried in accordance with a report drawn up by Professor Terrier (1) the surgeon on duty is in constant telephonic communication with the hospital, and a rota for duty is decided upon among the other surgeons on the list; and (2) a surgical guard is mounted by both the intern and extern pupils in surgery, and there must be at the hospital always one intern and two externs on duty. The rest of the staff, both nurses and porters, must have special surgical training. The operating-room is provided with all necessaries in the way of instruments, dressings, warming, lighting, &c. In taking over the charge of these urban ambulances the Municipal Council decided to build two new stations, the one on the right and the other on the left bank of the river; but the Commission proposed an even more thorough scheme—namely, three new stations on the right bank. One of these is in process of construction in the Rue Caulaincourt, another at the St. Honoré Market, and the third is at the St. Louis Hospital. The station on the left bank will be in an annexe of the Hôtel Dieu. The director of municipal affairs has, besides, taken steps to coördinate the ambulance service by the creation of a central office situated at the headquarters of the sanitary authorities. It will be on duty night and day, and thanks to it an ambulance will always come in answer to a call. This central service completes the connexion between the ambulance societies and the hospitals.

The Congress of Surgery.

The eleventh congress of the French Association of Surgery will open at Paris at the Faculty of Medicine on Monday, Oct. 18th, at 2 o'clock, under the presidency of Dr. Gross, Professor of the Faculty of Medicine at Nancy. Two questions have been submitted to the congress: first, Contusions of the Abdomen, by M. Demons, of Bordeaux; second, the Indication for Operation and Treatment of Cancer of the Rectum, by MM. Quenu and Hartmann, of Paris. Those intending to attend the congress or read papers are requested to send the titles and a short *résumé* of their papers, by Aug. 17th at the latest, to the general secretary, M. L. Picque, 8, Rue d'Isly, Paris.

June 22nd.

(FROM OUR OWN CORRESPONDENT.)

Premature Burial.

THIS subject has a peculiar terror for Italians. In cholera epidemics, particularly in those of 1866 and 1877, "apparent death" has led to the victim being put in a coffin and carried to the cemetery, where, by sheer accident, he has been rescued from the most horrible of fates in the nick of time. In his memorable treatise, written some twenty years ago, the greatest of recent Italian anatomists, the Florentine Filippo Pacini (discoverer of the "Corpuscula Paciniana"), describes several cases of "morte apparente" that came before him and the means by which he "restored" the "life" which had not really been extinguished. Since then physicians have been careful to allow some time to pass in cases of cholera collapse before granting certificates of death, and have practised Pacini's method of the intravenous injection of hot water charged with bay salt in solution before giving up all hope of bringing back the patient to conscious life. In its obituary notice of Pacini, who died in 1883, THE LANCET reviewed the treatise referred to, and, notably in the cholera epidemic which decimated some Italian cities in the following year, drew attention to the check imposed on the hasty burials so common in such visitations before Pacini's time. The rapid spread of cremation and the dread that under that system the "apparently dead" may be "disposed of" before they have a chance of regaining conscious life has, however, revived the subject, never altogether quite absent from the Italian mind, and at Milan on Thursday, the 10th inst., Signor Di Santostefano exhibited to an intensely interested audience an apparatus designed to give the reputed "corpse" a chance of receiving assistance. The apparatus, designed, however, for cases of interment, seems modelled upon that invented recently by Count Michael Karnichi, of Warsaw, who was specially induced to contrive it by the risk of inhumation during trance. As described by Signor Di Santostefano the apparatus brought under the notice of the Milanese audience is the following:—A tube is fitted to the lid of the coffin in which the body is laid and penetrates the lid by a small circular aperture situated just above the sternum of the body and connecting at the surface of the ground with a little metal box. Down through the tube descends a white metallic rod terminated by a ball which just touches the sternum of the "corpse." Supposing a sufferer from catalepsy to have been interred, he must, on coming to himself, as his first act draw breath, move a hand, or his whole body; he will thus inevitably displace the ball. The box situated on the surface of the ground will be overturned, giving air and light to the coffin; it will also set in motion a powerful electric bell, and will raise to the height of a metre and a half from the ground an alarm-signal visible at a great distance. It will finally admit of the "corpse's" calling for assistance by means of the tube, which partakes of the character of a speaking trumpet. Such is Signor Di Santostefano's account of the apparatus contrived in aid of the "buried alive," and, although highly ingenious, it is liable to so many adverse contingencies that it can be expected to fulfil its purpose only in a small percentage of cases. However, if it prove instrumental in rescuing even one victim to "premature burial" it will have amply justified its being put in operation.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Relation between the Nose and the Reproductive Organs in Females.

PROFESSOR KLEINWÄCHTER has published in the *Medizinische Presse* an article on a pamphlet which Dr. Fliess has written on the subject of the relation existing between the nose and the reproductive organs in females. It is stated that the inferior turbinated bones of the nose possess a corpus cavernosum the volume of which is liable to alteration under the influence of the spheno-palatine ganglion, and this ganglion receiving fibres from the carotid plexus through the deep petrosal nerve is in communication with the sympathetic nervous system which influences the sexual faculty. Opposite the middle turbinated bone there is on the nasal septum a pledget-shaped elevation with numerous blood-vessels and glands, the so-called tuberculum septi. These two structures, which Dr. Fliess calls the "genital places of the nose," become swollen, cyanotic, and very sensitive at the menstrual period. That form of dysmenorrhœa in which the pain continues after the commencement of the menstrual flow disappears at once if the two "genital places" of the nose are rendered insensible by a 20 per cent. solution of cocaine.

Hosted by Google

When an anæsthetic is applied to these places in only one nostril the pains disappear on only one side of the body; anæsthetisation of the inferior turbinated bones removes the abdominal pains in from five to seven minutes. By cauterising these places with trichloracetic acid dysmenorrhœa may be averted for a long time. That form of dysmenorrhœa which Dr. Fliess calls "nasal" is in a great many cases due to infectious diseases which cause hyperplasia of the nasal mucous membrane; but it sometimes arises from the fact that the corpora cavernosa of the nose do not decrease in volume after menstruation, and a congestion remains.

Post-graduate Instruction.

Courses of lectures, the attendance on which is limited to medical men in practice, are delivered in Vienna, but not in any other Austrian University. They have been introduced on the initiative of Professor Wagner, who has for a year been Dean of the Vienna Medical Faculty, and has appointed two months (August and September) during which they are delivered in two series by the most eminent *privat-docents* and assistants of the faculty. Each course lasts four weeks, and the fees vary from twenty gulden (£1 17*s.*) to fifty gulden (£4 13*s.*), according to the subject. The first series begins on August 2nd and comprises the following courses: Pathological Anatomy, Bacteriology, Experimental Pathology, Pharmacology, Internal Medicine, Neuro-pathology, Diseases of Children, Ophthalmology, Laryngology, Diseases of the Ear, Dermatology and Syphilis, Oostetrics and Gynæcology. The second series, beginning on September 1st, includes the following courses: Anatomy, Pathological Anatomy, Bacteriology, Experimental Pathology, Forensic Medicine, Internal Medicine, Surgery, Ophthalmology, Diseases of the Ear, Dermatology and Syphilis, Obstetrics and Gynæcology. These courses are likely to be preferred by medical practitioners to those delivered during the session from October to July, as they are not attended by students.

Bubonic Plague.

At the last meeting of the Medical Society Dr. Albrecht gave an account of his experience of plague acquired by an observation of 247 cases in Bombay. He said that plague is infectious and shows no resemblance to any other disease. Its most frequent form is the septicæmic-hæmorrhagic, beginning with a primary hæmorrhagic bubo in the inguinal, axillary, or cervical region, this bubo being accompanied by œdema of the surrounding parts; there are also hæmorrhages into various organs, changes in the lymphatic glands, symptoms of degeneration in the parenchymatous organs, and a characteristic enlargement of the spleen. Sometimes there is no primary bubo, but all the lymphatic glands become swollen. The bubo suppurates after nine days; when it bursts or is opened and the pus is evacuated the glandular substance is found to have disappeared and only an empty capsule remains. A second form of the disease is marked by pyæmia and numerous deposits in the internal organs; in these cases post-mortem examination shows embolic centres in the lungs, liver, and kidney, together with characteristic hæmorrhage into the walls of the gall-bladder. Sometimes the disease takes the special form of primary pneumonia marked by confluent inflammatory centres, without any swelling of the lymphatic glands. The bacillus is found in the blood and the sputum, but not in the fæces or urine. It cannot be stained by Gram's method, it has a capsule, and is easily destroyed by unfavourable conditions, such as exposure to a high temperature.

June 19th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Twelfth International Medical Congress: the Free Railway Passes.

As already announced in THE LANCET, the Russian Government has decided to grant free railway passes on all Russian railways to members of the International Congress. In the case of foreigners the ticket will be available from any frontier station chosen by the member to Moscow and back. The return route need not be the same as the outward route, but the member must, in applying for a ticket, state which route he intends to follow both outward and homeward. It had at first been announced that this would not be required of members, and that it would be open for them to select even at the last moment the route by which they would return from Moscow, but the Executive Committee has just issued a statement correcting the first announcement and adding that only in exceptional circumstances can the return route for which a ticket has been issued be altered. The reason of this arrangement is obvious; the railway authorities are desirous of having some approximate idea of the numbers of passengers who will be leaving Moscow after the Congress by each particular line of railway and of providing accommodation accordingly. Intending members of the Congress are therefore requested, in writing to Professor Roth (the general secretary, Twelfth International Medical Congress, Moscow) to obtain the free railway passes, to state in their letters which routes they wish to follow both going to and returning from Moscow. The committee has received from the Government 7000 such free passes. The passes will be available on any date until Sept. 10th (22nd) instead of only until the 1st (13th) of that month, as at first announced. Members who have received their free railway tickets are requested to present them at the frontier station, where they will be stamped; they may also be asked to show them by the railway officials at any part of the journey. These trifling formalities will present no difficulties to the foreigner, as at each principal frontier town a committee of medical men (principally army surgeons) has been formed with the express object of assisting foreigners on their journey. In addition, the Custom House authorities have been approached by the committee and asked to "deal gently" with members of the Congress. The free railway ticket entitles the holder to carry one *pood* (36 lb.) of luggage free of carriage. Before leaving Moscow the return ticket must be stamped at the office of the executive committee to the effect that the holder is a *bonâ-fide* member of the Congress, and it will have to be presented at the booking-office of the station of departure to be stamped with the date.

The Ladies' Committee.

As a considerable number of lady guests may be anticipated a committee of ladies has been formed to provide for their comfort and amusement during their visit to Moscow. This Ladies' Committee has been taken under the gracious patronage of the Grand Duchess Sergius, the granddaughter of Queen Victoria and sister of the reigning Empress. The president of the committee is Madame Skliffosofski, who is assisted by Madame Kojevnikof and Madame Pashutin. This committee proposes to organise a small exhibition of women's work, and hopes to make this as representative as possible of the position and activity of women in Russia. The exhibition will be open during the period of the Congress. Members who expect to be accompanied by ladies are particularly requested to communicate the fact to the general secretary, Professor Roth.

The Arrangements in St. Petersburg.

The committee formed in St. Petersburg to arrange for the reception of members of the Congress and their proper entertainment in this, the second capital of the Russian Empire, has already announced a number of interesting engagements for the days succeeding the close of the Congress. The Congress in Moscow will end on the 14th (26th) August; on the 16th (28th), a Saturday, there will be a reception of members by the St. Petersburg medical societies and the profession in general; this will be held in the Salle de Noblesse, the largest and handsomest hall in St. Petersburg. On Sunday, the 17th, there will be an excursion to Peterhof, where there are more than one Imperial palace and a very beautiful park, the fountains in which rival the famous fountains of Versailles. Supper will be served in Monplaisir, a picturesque little Imperial summer-house, dating from the time of Peter the Great and built close to the waters of the gulf. For those members who do not go to Peterhof there will be on the same evening a reception or "rout" given by Her Highness the Princess of Oldenburg. On Monday, the 18th, the new museum at the Imperial Academy of Military Medicine, named after the great surgeon, Pirogof, will be opened in state in the morning, and in the evening the town council will hold a reception. The two following days are allotted to an inspection of some of the medical and other institutions of interest in the city.

The Pirogof Statue in Moscow.

One of the events of the Congress week in Moscow will be the formal unveiling of the new statue to Pirogof in front of the principal entrance to the clinique. The proposal to erect such a monument was made in the year 1891 and a

Hosted by Google

subscription list was started; the sum collected amounted in 1895 to 12,000 roubles (about £1300), and the work was entrusted to Mr. V. O. Sherwood, member of the Academy of Arts. The statue is already complete, but a further small sum of money is required for paving the space about the statue and adding a chain or railing round it. For this 1600 roubles are required, and this sum will probably be voted by the town council of Moscow. Pirogof's relations with Moscow were of the most intimate kind, as may be gathered from his own words, which have been chosen to appear on the pedestal of the monument: "The city of Moscow, in honouring me with the title of honorary citizen, have realised the secret dream of my youth, when I was prepared to dedicate the whole of my life solely to Moscow, the place of my birth and of my education."

The Recent Jenner Centenary.

The Russian National Health Society, at their recent annual meeting, awarded the gold medal of the society to Dr. Hubert for his Jenner Centenary volume on "Small-pox and Vaccination," which was reviewed in THE LANCET of April 17th. The gold medal is given once in two years, and a silver medal annually. At the same meeting a number of foreign honorary members were elected, and among them the Epidemiological Society of London as a whole received the honorary membership of the Russian society.

The Russian Census.

The preliminary results of the first complete Russian census ever taken have just been published. The total population of the empire in January last, the date of the census, was 129,211,113; the number of males was 64,616,280, and of females 64,594,833. This proportion of the sexes, in which the males slightly exceed the females, is worthy of remark. Previous attempts to arrive at a knowledge of the number of persons in the empire were made in 1851, when the population was reckoned at over 67,000,000; in 1858, when the figure had risen to over 74,000,000; and in 1885, when it had increased to 108,819 332.

June 5th (17th).

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Recent Annual Medical Conference held at Nelson.

THE New Zealand Medical Association is in name a colleagueship of the past, and we are now inaugurated as a branch of the British Medical Association. How this change has come about is not by any means clearly seen by the majority of the members of the profession practising in this colony. I have already maintained that it is a misfortune that circumstances have so come about that at the present time we have no representative journal of our own. The *New Zealand Medical Journal* was edited ever since its inception in a most befitting manner. It had a considerable credit balance at the time of its decease—viz., at the end of the year 1896. It was well supported by the profession, and numerous original articles, dealing with a vast variety of medical, surgical, and general topics, have from time to time appeared in its pages. In was, in fact, a medium of recording special work in the colony, and right well did it carry out its purpose. In its place we have a limited space allocated to us in the *Australasian Medical Gazette*—a journal printed on the other side. How long this arrangement will be considered satisfactory to the members of the profession practising here remains to be seen, but I venture to predict that ere long we shall find it necessary to ventilate our thoughts through the medium of a medical journal edited in New Zealand. Living so far away as we do from "home" perhaps the determination to unite ourselves with the British Medical Association and be subservient to its rules and ordinances will turn out a satisfactory arrangement. It has, however, been found necessary to frame certain by-laws which shall govern our transactions in the colony apart from the ordinary rules of the British Medical Association.

General practitioners in New Zealand—which looks such a small speck on the map, but which is about the size of Great Britain and Ireland minus Wales—live a very long way apart, and have in each locality many miles of surrounding district to cover in their daily work. In these circumstances it is looked upon as very improbable that a very large attendance of the profession will be likely to congregate on the occasions of the annual medical conferences, and this has certainly been the experiences of the past. The year 1897 will be remembered, however, for attracting to Nelson a very representative conclave of medical men from all parts of the colony, to see the old order of affairs superseded and the new state of mission inaugurated.

The majority of the Wellington and the West Coast of the North Island contingent left the empire city on board the Union s.s. *Wainui* on Sunday evening, March 7th, and were rewarded by having a most glorious passage through the "French Pass," no antidotes for *mal-de-mer* being necessary. We had a travelling theatrical company on board and things from the start were characterised by recitations and joviality. Not so rosy a time, however, did the remaining members of the conference experience, who elected to leave the same port on the following day on board the s.s. *Corinna*, for a sou'-wester suddenly sprang up, and by the time the good ship had reached the wharf at Nelson those on board were prostrate, for the storm had played more havoc in the "garden of New Zealand" than any similar visitation during the past thirty years.

Such was our first night at Nelson, the howling wind and driving rain wafting away sweet sleep from most of us and from many of the townsfolk. As the dawn of Tuesday, March 9th, appeared the gale suddenly lessened and shortly gave place to bright sunshine and a crispness of the air which enabled us to visit with pleasure during non-working hours the many beautiful scenes which this part of New Zealand presents. It also enabled us to enjoy to the full the kindly hospitality of our Nelson medical brethren, who had so arranged social gatherings (including a delightful picnic to Cable Bay) and dinners that our time was fully occupied during the week in scientific work and recreative enjoyment which none of us will soon forget. Father Mahoney's hospitality and attention to us must be specially referred to—a genial, kindly gentleman (who has done so much to benefit his flock and the public of Nelson as a whole) that we would all like to give him a "retaliation." It is with gentlemen of his position, endowed with light and understanding, that intercourse with members of the medical profession brings about matters for the public well-being.

Tuesday, March 9th, at 3 P.M., was the date fixed, and the Museum at Nelson the rendezvous, for the introductory address, which related to affairs deferred from the New Zealand Medical Association, correspondence, &c., and notices of motion in connexion chiefly with the vexed "club question." A long and very interesting discussion took place on this latter subject, and it was ultimately decided to leave the matter in the hands of the Provisional Council to report on. Now, as this is one of the most important questions which concerns the members of the profession as well as the public, it was decided by the Council (which was afterwards elected) "to draw up certain suggestions and to send a copy to each practitioner in the colony and to the secretary of each section of the New Zealand Branch of the British Medical Association to report and give information on." This was carried unanimously by the Council. The following were elected members of the Provisional Council: Dr. Scott (Auckland), Dr. Saunders (Wanganui, as delegate for the Hawke's Bay Branch), Dr. Collins (Wellington), Dr. Graham-Campbell (Christchurch), and Dr. Mackie (Nelson).

At 8 P.M. the same evening Dr. Cleghorn, the President for 1897, delivered a thoroughly practical address on the relationship in this colony between the profession and the public. I trust that it will bring forth the fruit in due season which its thoughtful preparation so well merits. That Dr. Cleghorn's address was appreciated by his medical *confrères* was significant by the frequent plaudits which occurred during the course of his remarks. The President received a hearty vote of thanks for his address.

The following papers were read at the meeting: "New Methods of Diagnosis and Treatment of Chronic Disorders of the Stomach," by Dr. Colquhoun (Dunedin); "Osteomyelitis," by Dr. W. Collins (Wellington); "Ununited Fracture of the Humerus: Successful Treatment after Sixteen Months of Solution of Continuity by a Modification of Lane's Method," by Dr. G. R Saunders (Wanganui); "Early Ectopic Gestation," by Dr. F. Batchelor (Dunedin); "Albumose in the Urine," by Dr. Fyffe (Wellington), who also contributed a very interesting paper on a Case of Operation for Perforation of the Stomach. Dr. Scott also gave a demonstration of administration of gas and ether.

A most delightful picnic to Cable Bay, the site of the submarine cable house, wound up a very successful week.

April 15th.

Hosted by Google

Obituary.

MATTHEW CHARTERIS, M.D. EDIN., F.R.S. EDIN.

WE announced in our issue of June 12th with deep regret the death of Dr. Matthew Charteris, Professor of Materia Medica and Therapeutics in the University of Glasgow, who passed away on June 7th at the little village of Comrie in Perthshire, where he had gone to recruit after a severe attack of influenza. He was born in 1840 in the lovely district of Wamphray, Dumfries-shire, and received his early education from his father, who was schoolmaster there. He afterwards attended the arts classes at the University of Edinburgh, where he distinguished himself as a classical scholar; but presently deserting these literary pursuits for the study of medicine, he graduated as M.D. in 1863. In the same year he obtained the Licence of the Royal College of Surgeons of Edinburgh, and then proceeded to Paris, where he attended the clinics of the leading men. He also worked for a time in London, where he held several junior medical appointments. Returning to Scotland he settled at Airdrie, but soon left there for the neighbouring city of Glasgow, where he rapidly acquired a high reputation and an extensive practice. In 1874 he became a Fellow of the Faculty of Physicians and Surgeons of Glasgow, and two years afterwards was appointed to the important post of Professor of the Practice of Medicine in Anderson's College. Previously to this he had been elected one of the honorary physicians to the Royal Infirmary, where he rapidly became popular with the students for his unusual powers of clinical teaching. In these posts he had acquired so outstanding a reputation as a teacher and therapeutist that on a vacancy occurring in 1880, the Crown appointed him to the Chair of Materia Medica and Therapeutics in Glasgow University, a position which he filled with honour and dignity for seventeen years. On his appointment he took up the work of the chair heartily and enthusiastically, and getting rid as far as possible of the old-fashioned trammels and traditions surrounding materia medica, he endeavoured to make his lectures on therapeutics a living and practical part of the medical curriculum—an endeavour in which his students will heartily admit that he was entirely successful. Besides being actively occupied with practice and teaching he engaged, as time allowed, in a number of scientific researches. The best known of these is his investigation into the action of the impurities found in sodium salicylate. During the first of the recent epidemics of influenza he was much struck by observing the occasional very depressing effects of this drug, and after prolonged inquiry he was able to show that this was due to the presence in varying quantity of one of the varieties of cresotic acid. Pure or "natural" salicylate he found to be comparatively harmless, and as an outcome of his researches great practical improvements have taken place in the manufacture of salicylic compounds. He also investigated the effects of copper when used as a colouring agent for preserved fruits and vegetables, this like all his other contributions showing a distinctly practical bent of mind. He was a frequent contributor to THE LANCET and to the medical press generally, and comparatively recently had written on the treatment of rheumatism and of sea-sickness. He was recognised as an authority on climatic treatment and health resorts—a subject on which he had written largely, being the author of a well-known book and of the article on Treatment by Climate in Quain's Dictionary of Medicine. He was a Fellow of the Royal Society of Edinburgh and a vice-president of the British Balneological Society, and had lately been nominated a vice-president of the International Medical Congress to be held this year at Moscow. He had a deep sense of the importance of the clinical teaching of thereapeutics and of pharmacology as being calculated to train students in rational methods of treatment as opposed to dogmatic and empirical methods, and for some years past it was a matter of the deepest regret to him that no beds were allotted in the Western Infirmary to his university chair, so that he was unable to illustrate his lectures by his practice. He made a determined effort to alter this state of things, but without success—a result to be regretted both on account of the infirmary and of the University. Personally Matthew Charteris was one of the kindest and most amiable of men—simple, and unassuming as regards his own position and attainments, but appreciative and sympathetic towards the work of others. He took an active part in university affairs, and was greatly beloved by his students for his unvarying kindness to them in every relationship. Many of his old pupils owe to his interest in them their first start in their medical career after graduation, and he will be greatly missed not only in the University, but by a wide circle of friends in Glasgow. He was a keen fisherman and golfer, and a good billiard player. He kept up throughout life a strong interest in the Latin poets, the result no doubt of his early training under his father. He leaves a widow and three grown-up sons.

THOMAS HAMILTON, M.D. EDIN.

BY the death of Dr. Hamilton, who passed away at the ripe age of eighty-three years, Kelso has lost a highly esteemed practitioner of the old school. The deceased was educated at the Edinburgh High School and at the University of Edinburgh, where he took the degree of M.D. so far back as the year 1838. For many years he had an extensive, though it must be confessed not very lucrative, practice, and among the many offices he filled was that of medical officer to the Kelso Union Poorhouse. He was an earnest Presbyterian and was for nearly fifty years an elder. He was a good linguist and classical scholar, while his unfailing kindness and courtesy endeared him to all classes with whom he came in contact. The funeral, which took place on June 6th, was attended by a large number of friends and former patients. Although he had for some time retired from active practice he continued to take a prominent part in town affairs, and his loss will be greatly felt in Edinburgh where he had resided for many years.

HUGH MOSS, J.P., M.D. ST. AND., M.R.C.S. ENG., L.S.A.

THE news of the death of Dr. Hugh Moss, of Congleton, Cheshire, at the age of fifty-eight years, has been received with great regret by many friends and acquaintances in both public and private capacities. His health had been failing for some months, but he was able to continue active work up to the last. Whilst seeing a patient on the morning of May 28th he was seized with apoplexy and died in a few hours. Dr. Moss qualified M.R.C.S. Eng. and L.S.A. in 1862, and in the same year obtained the M.D. degree of St. Andrews University. For over thirty years he was medical officer to Congleton union, and enjoyed an extensive country practice. Dr. Moss took much interest in municipal affairs, and was for three consecutive years mayor of the borough, carrying out his duties with great assiduity. He devoted much of his leisure time to music, and was especially proficient as a player of the flute and violin. He was held in the highest esteem both on account of his personal charm and professional ability. His loss is deeply felt by a large circle of friends and patients, more especially perhaps by the sick poor, to whom he was ever most unremitting in his care and attention. The funeral was a public one, attended by the mayor and corporation and a large number of townspeople. Dr. Moss leaves a widow and four daughters.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the examination in June the following candidates passed in the subjects indicated:—

Surgery.—P. D'E. Burrell, St. George's Hospital; G. F. McCleary, Cambridge University and Middlesex Hospital; E. J. O'Meara (Sections I. and II.), Guy's Hospital; A. H. Turner, London Hospital; and J. H. Whitaker, Belfast.

Medicine.—J. T. Brickwell, Guy's Hospital; F. R. Greenwood, St. Bartholomew's Hospital; G. F. McCleary, Cambridge University and Middlesex Hospital; W. Mawer, St. Bartholomew's Hospital; E. J. O'Meara (Section II.), Guy's Hospital; and T. H. B. Yorath, Guy's Hospital.

Forensic Medicine.—J. T. Brickwell, Guy's Hospital; J. Cater, King's College Hospital; P. H. Collingwood, St. Thomas's Hospital; F. R. Greenwood, St. Bartholomew's Hospital; T. Jones, Middlesex Hospital; G. F. McCleary, Cambridge University and Middlesex Hospital; and E. L. C. Muspratt, King's College Hospital.

Hosted by Google

Midwifery.—J. T. Brickwell, Guy's Hospital; J. Cater, King's College Hospital; T. Jones, Middlesex Hospital; H. Lewkowitsch, Breslau; G. F. McCleary, Cambridge University and Middlesex Hospital; and A. E. Seller, London Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—Messrs. J. T. Brickwell, P. H. Collingwood, H. Lewkowitsch, E. J. O'Meara, W. Mawer, G. F. McCleary, E. L. C. Muspratt, A. E. Seller, and J. H. Whitaker.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on June 18th, in addition to the honorary degrees conferred on the colonial Premiers and other distinguished persons, the following medical degrees were granted:—

Doctor of Medicine.—Joseph Blumfield, B.A., Caius; and Ernest Noël Nason, B.A., Downing.

Bachelor of Medicine.—L. P. Black, M.A., Trinity Hall; J. M. Martin, B.A., St. Peter's; H. B. Milsome, B.A., Trinity; W. Irving, B.A., Caius; S. H. Long, Caius; A. Mackenzie, B.A., Caius; W. B. Dove, B.A., Christ's; W. E. Manby, B.A., Christ's; H. Roper, B.A., Christ's; H. J. R. Twigg, B.A., Christ's; J. C. Muir, B.A., Emmanuel; and G. B. Muriel, B.A., Downing.

Bachelor of Surgery.—H. B. Milsome; P. J. A. Seccombe, M.A., St. John's; J. M. Martin; W. Irving; A. Mackenzie; W. B. Dove; W. E. Manby; H. Roper; H. J. R. Twigg; J. C. Muir; and G. B. Muriel.

Professor Allbutt has been appointed to represent the University at the forthcoming International Medical Congress in Moscow. Mr. E. W. MacBride has been appointed an Additional Examiner in Elementary Biology for the M.B. degree. There were 145 candidates at the examination just completed. In presenting Sir John Kirk, M.D. Edin., F.R.S., for the honorary degree of Doctor of Science on June 17th, the Public Orator referred to him as "Livingstonii comitem fidelissimum, Livingstonii adiutorem optimum, virum scientiarum laude insignem, Africæ denique in litore orientali per annos plurimos Britanniæ procuratorem indefessum."

OPENING OF THE NEW COUNTRY BRANCH OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC AT EAST FINCHLEY.—On Wednesday, June 16th, as we briefly mentioned last week, the Duchess of Albany performed the ceremony of opening the new convalescent home which the board of the hospital have erected at East Finchley in place of an old and less commodious building. A large number of visitors travelled from King's Cross by special train. After a short religious service an illuminated address was presented to Her Royal Highness, and at the request of Mr. G. W. E. Russell, she declared the building open. The Duchess was afterwards conducted over the building by Dr. Buzzard, Dr. Gowers, and Dr. Ormerod, and showed the greatest interest in all the arrangements of the hospital, and conversed with many of the patients. The hospital in Queen-square, of which this is a branch, was one in which the late Duke of Albany took active interest, and after his lamented death Her Majesty the Queen approved of the name of "Albany Memorial" being given to the hospital. It must have therefore been gratifying to Her Royal Highness to find that the institution, which owed so much to the Duke, has been so successful that it has been obliged to enlarge its borders. The new hospital stands in a large garden at the edge of the well-wooded slope which extends northward from Hampstead and is admirably adapted for its purpose. It is intended to accommodate thirty female and ten male patients. Not only epileptics, but patients convalescent from other forms of disease of the nervous system are sent from the parent hospital. It is to epileptics particularly that the home will be a boon, as in consequence of their infirmity they are not admissible to ordinary convalescent homes. Nearly all the rooms are on the ground floor, making movement about the house easy for those who are suffering from some form of paralysis, and protecting epileptics from the risk of injuring themselves by falling downstairs during an attack. The wards are very bright and well ventilated. There is an adequate resident nursing staff, and the patients are visited every week by two of the physicians, or in an emergency by the local officer, Dr. Hicks.

THE Brighton corporation on June 17th passed new by-laws for dealing under penalties with small occupiers who sub-let a part of their houses. This is, in the opinion of Dr. Newsholme, the medical officer of health, one cause of the high death-rate in one or two of the wards of the borough. Competitive plans are being invited for a large number of artisans' dwellings to be erected by the Council. The borough waterworks last year made a gross profit of £33,686; £8500 go to the relief of the rates.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health (Scotland) Bill.

THERE is every prospect of ample discussion on the report stage of this Bill with regard to the amendments made by the Grand Committee putting the sanitary inspector on the same footing as the medical officer of health in deciding what are nuisances and other points in connexion with public health administration. Formal proposals to strike out these amendments have been given notice of by Sir William Priestley and Sir Walter Foster.

The Scottish Universities Commission.

Having regard to what was said at the recent meeting of the General Medical Council with reference to the ability of the Scottish Universities to get from the Scottish Universities Commission an ordinance empowering them to exercise discipline upon their graduates, the assurance given by Mr. Hanbury, Secretary to the Treasury, on Friday, June 18th, in the House of Commons is of some importance. Mr. Hanbury's attention was called by certain of the Scotch Members to the litigation going on between the University of St. Andrews and the College of Dundee, and he stated in explicit terms that until this litigation is concluded and the point at issue settled the Scottish Universities Commission cannot come to an end. Not only so, but provision is made in the estimates of the year for the continued existence of the Commission.

HOUSE OF COMMONS.

THURSDAY, JUNE 17TH.

Education for Blind and Deaf Children.

Sir John Gorst made a statement on this subject when introducing, at this sitting of the House the vote for public education in England and Wales. He stated that the sum now earned by the schools for giving this education amounts to £17,627 a year, the increase in the present year being no less than £5335. The grants allowed were £3 3s. per scholar for ordinary elementary education and £2 2s. per scholar for manual instruction and industrial training. In 1894–95, while 3121 scholars earned the former grant, only 1937 earned the latter; but in 1895–96, out of 3742 who earned the grant for ordinary elementary education, no fewer than 3611 earned the grant for manual instruction and industrial training. These figures showed, he said, that under the improved arrangements of the present day almost every blind and deaf child not only received ordinary elementary education, but also received manual instruction, which in many instances enabled them to earn their own livelihood and become valuable members of society. This result of the new Act, which was to some extent an experiment, was highly satisfactory and ought to encourage Parliament and the country in proceeding in this and in analogous cases with some degree of confidence.

Metropolitan Poor-law Children.

Mr. James Stuart, in the course of the debate on the Education Vote, urged the Education Department to take within its cognizance the poor-law schools of London. Sir John Gorst replied that where guardians in other parts of the country had sent the children to the ordinary public schools the best results had been obtained; but in these large pauper schools in London the education was very inferior and far short of the requirements of the Education Department. Not only so, but if the Department undertook their inspection it would have no security that the recommendations of its inspectors were carried out. The only way to break up these large schools was for the guardians to send the children to the ordinary schools, and in that effort he wished them God-speed.

FRIDAY, JUNE 18TH.

Experiments on Living Animals.

During the debate on the Home Office Vote Mr. Weir made allegations of cruelty in connexion with vivisection, and read extracts from a letter on the subject. The Home Secretary (Sir Matthew White Ridley) undertook to inquire into the matter, but said he did not believe there was any foundation for the allegations. During the course of the last year or two he had received only one or two complaints as to the way the operations were carried on and as to alleged cruelty or irregularity under the Act. The charges made were not substantiated in any case, and he had every reason to believe that the Act was humanely and properly administered, and that the two inspectors were thoroughly up to their work. They paid surprise visits and took every means to secure the efficient carrying out of the Act.

MONDAY, JUNE 21ST.

Food Products Adulteration.

Mr. Balfour said, in reply to questions by Mr. Jeffreys and Major Rasch, that while he could give no specific pledge as to when the Bill dealing with the adulteration of food products would be introduced, he hoped the introduction would take place at no distant date—probably next week or the week after.

Naval Hospital Diet Sheets.

Dr. Tanner asked the First Lord of the Admiralty whether any, and if so what, system was pursued with regard to the audit of all naval hospital diet sheets.—Mr. Goschen replied that the various diet sheets were compiled by the medical officers of wards, who entered personally on them daily the diets they had ordered. These sheets were examined in the office of the principal medical officer in charge of the hospital, who certified on the quarterly provision account that this had been done. The audit of hospital accounts, which included that of diet sheets, had been conducted for some time past by the controller and auditor-general.

Dog Muzzling Orders.

Mr. Walter Long, President of the Board of Agriculture, said, in

Hosted by Google

reply to Sir Charles Dilke, that he had caused a special inquiry to be made as to the application of the dog muzzling order to sheep dogs while working, the result of which went to show that no really serious inconvenience was caused by requiring these dogs to be muzzled in districts in which such a measure was necessary. This view was confirmed by the past experience both of the Board of Agriculture and many local authorities when muzzling regulations had been made. Moreover, the proposed exemption would seriously impair the efficiency of the orders now in force and render it necessary for them to be continued for a longer period than he hoped would be necessary.

The London Water Question.

Mr. Chaplin said he was informed that the Royal Commission on the London Water-supply held their first meeting on May 29th, when temporary accommodation was provided for them. Offices had since been assigned to the Commission, and he was advised that the inquiry was proceeding.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BAILEY, J. G., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Huddersfield Infirmary.

BARTLETT, R. C., L.R.C.P. Lond., F.R.C.S., has been appointed Medical Officer of Health by the Ramsey Rural District Council.

CARWARDINE, THOMAS, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Bristol Royal Infirmary.

EATON, JAMES, M.R.C.S., has been re-appointed Medical Officer of Health by the Grantham Rural District Council.

FOX, G. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Walsall Rural District Council.

GIBSON, W. R., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Infirmary of the St. Saviour's Union, London.

GILL, F. A., M.B., C.M. Aberd., has been appointed an Assistant Medical Officer to the Manchester Prison.

GRINDLAY, G., M.B., C.M. Edin., has been appointed Medical Officer for the Kingswinford Sanitary District of the Stourbridge Union.

HASLAM, W. F., F.R.C.S., has been appointed an Examiner in Anatomy for the Fellowship of the Royal College of Surgeons.

LAKE, RICHARD, F.R.C.S., has been appointed Surgeon Laryngologist to the North London Hospital for Consumption, Hampstead.

LATTER, CECIL, M.D., B.C., B.A. Cantab., has been appointed Medical Officer to the Victoria Hospital, Folkestone, vice F. Eastes, deceased.

MACDONALD, J., M.B., C.M. Glasg., has been re-appointed Medical Officer for the burgh of Saltcoats.

MAYNARD, EDWARD FORSTER, M.D. Edin., has been appointed Assistant Physician to the Sussex County Hospital.

MCCLELLAND, W. C., M.B., M.Ch. Syd., has been appointed a Senior Resident Medical Officer for the Sydney Hospital, New South Wales.

MONAHAN, P. F., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Kiltormier Dispensary District.

PASTEUR, W., M.D. Lond., has been appointed Consulting Physician to the North-Eastern Hospital for Children, Hackney-road.

ROBERTS, S. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Acton Union, vice W. G. Cresswell, resigned.

SLADER, G. W. B., L.R.C.S. & L.M. Irel., L.S.A. Lond., has been appointed Medical Officer for the Blyton and Corringham District of the Gainsborough Union, vice D. Mackinder, resigned; also Surgeon to the Manchester, Sheffield, and Lincolnshire and Great Eastern Railways, vice D. Mackinder, resigned.

SOPER, R. W., M.R.C.S., has been re-appointed Medical Officer by the Dartmouth Town Council.

THOMAS, J. T., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Combined Sanitary Districts of Leicester and Rutland, vice J. A. Turnur.

WARDALE, J. D., M.B. Durh., has been appointed Surgical Registrar to the Royal Infirmary, Newcastle-on-Tyne.

WARRINGTON, W. B., M.D. Lond., has been appointed an Honorary Assistant Physician to the Liverpool Hospital for Consumption, vice T. Bushby.

WINGATE, D., M.B., C.M. Glasg., has been appointed Medical Officer for the Easington Sanitary District of the Easington Union.

WOODSIDE, W. A., L.R.C.P., L.R.C.S. Irel., has been appointed a House Surgeon to the Meath Hospital and County Dublin Infirmary.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which is completed with the issue of to-day, will be given in the next number of THE LANCET. It is intended, in future, to include the Index and Title page for each past half-yearly volume in the first number of the succeeding volume, instead of in the last number of the volume itself, as heretofore.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Could any of your readers assist me in finding a home for an imbecile man? He is thirty-five years of age, quite harmless, has no paralysis or fits, can feed and dress himself, but requires a certain amount of supervision. His parents are aged, and would invest a sum sufficient to secure the regular payment of £1 per week, but could not afford to pay more. Naturally, they are anxious to find a home for their only son where he would be cared for and not abused. Any help in this matter would greatly oblige, Yours faithfully,

June 23rd, 1897. M.D.

"THE SUPPLY OF TETANUS ANTITOXIN."

To the Editors of THE LANCET.

SIRS,—With reference to the letter by Mr. Buck in THE LANCET of June 12th regarding the difficulty experienced in obtaining serums from the wholesale agents in London, we would like to point out to you that we are acting as agents for the supply of serums issued by the Pasteur Institute in Paris, and that these can be procured in London at any time by wire from our west-end depôt, Mr. F. A. Rogers, successor to late Corbyn and Co., 327, Oxford-street; and from another depôt, Messrs. Alsop and Quiller, Sloane street, S.W. We would also like to point out to you that in Edinburgh, Glasgow, Belfast, Dublin, and other large towns we have depôts where these serums are stocked; and if your correspondent will put himself in communication with us we shall be pleased to give him a list of establishments from which serums can be procured without any delay at any time. Thanking you in anticipation of your kindly publishing this information,

We are, Sirs, yours faithfully,

OPPENHEIMER, SON, AND CO., LTD.
(*per* A. W. BALL, Director).

14, Worship-street, E.C., June 12th, 1897.

To the Editors of THE LANCET.

SIRS,—Our attention has just been drawn to the letter signed by Mr. Arthur H. Buck in THE LANCET of June 12th. Had Mr. Buck taken the trouble to consult your advertisement pages he would have seen that for months past we have at frequent intervals had advertisements headed "Sunday," specially drawing attention to the fact that all the antitoxic serums of the British Institute of Preventive Medicine, &c., when wanted from us on that day, should be ordered from our Vere-street branch, the telegrams to be addressed, "Hanburys, Vere-street, London." A line drawing attention to this Sunday supply has appeared in our antitoxin advertisement every alternate week, and we think Mr. Buck might at least have taken the trouble to ascertain the facts of the case before publishing a statement which leads to an erroneous conclusion. May we take this opportunity of adding that any of our goods required on Sunday, or at night, should be ordered from our Vere-street establishment and not from Plough-court or Bethnal-green?

We are, Sirs, yours faithfully,

ALLEN AND HANBURYS, LIMITED

June 22nd. 1897. (*per* FREDERICK J. HANBURY, Director).

POISONED BY BUTTERCUPS.

IT is not generally known that the buttercup which is such a favourite flower with children has poisonous qualities, yet such is the case, and an inquest has recently been held on a boy who after eating some buttercups died within a few hours with all the symptoms of irritant poisoning. The buttercup belongs to the Ranunculaceæ, and nearly all the members of this group possess poisonous qualities, chiefly of an irritant nature, though in a few narcotic principles are to be found. The virulence of the poisons varies very much, but there are very few individuals of this order which are inert. The various species of buttercups have all irritant properties, and in the absence of better drugs they have occasionally been used as vesicatories. Cows avoid buttercups, but hogs and some other animals can eat them with impunity. The active principle is volatile, so that when the buttercups are dried with hay or exposed to the air they become inert. Luckily the buttercup, though pretty to look at, does not usually tempt children to eat it wholesale, otherwise cases of poisoning might be less rare than they fortunately are at present.

Stockton.—We are well known to disapprove strongly of the association of medical men with these medical aid associations, but there is nothing in this friendly society that calls for particular notice from a professional point of view. The sums paid by the members are higher than in many such "clubs," but possibly the medical men are none the better paid for that.

A GOOD WAY BACK.

To the Editors of THE LANCET.

SIRS,—It may be of interest at the present time to readers of THE LANCET to refer them to the volume for 1837, where they will find an account of the death of my father's uncle, William Lynn (who, like my father after him, was for many years one of the surgeons of Westminster Hospital), which took place suddenly on June 24th in that year, four days after the Queen's accession. He had been visiting a friend at Bloomsbury, having been driven there in his carriage from Clapham, where he resided, and died when just about to enter it again for the return journey. During the visit much of the conversation naturally fell upon the recent death of the King (William IV.), and in the course of it Mr. Lynn remarked that he well remembered the death of George II. when he was about seven years of age. This carries us back a good way. I am, Sirs, your obedient servant,

Blackheath, June 14th, 1897. W. T. LYNN.

AN APPLIANCE FOR THE DEAF.

To the Editors of THE LANCET.

SIRS,—Some time ago I saw an appliance spoken of—I think in THE LANCET—to assist in cases of dulness of hearing. It was, I believe, of aluminium, and was designed to hang from a garment so that both hands might be free. All about it has quite escaped me, and you will have my best thanks if you can give me the name of the maker or of the firm supplying it. I am, Sirs, yours truly,

May 29th, 1897. J. W. W.

Lex.—(1) We cannot find any decision. Section 42 of the Public Health (Scotland) Act is as follows: "Where a hospital or place for the reception of the sick is provided or exists within the district of a local authority the sheriff or any magistrate or justice may, on the application of the local authority, with the consent of the superintending body of such hospital or place, by order on a certificate signed by a legally-qualified medical practitioner, direct the removal to such hospital or place for the reception of the sick, at the cost of the local authority, of any person suffering from any dangerous, contagious, or infectious disorder, and being without proper lodging or accommodation, or lodged in a room occupied by others besides those in attendance on such person, or being on board any ship or vessel, or may direct the removal from the room occupied by such person of all others not in attendance on him, the local authority providing suitable accommodation for such other persons." Our correspondent should note, however, that a county council, as such, is not the local authority for carrying out the Public Health Acts, excepting where the county is not divided into separate districts. Wherever there are such districts the district committee is the local authority. (2) Section 121 is as follows: "The constabulary and police force in their respective jurisdictions shall aid the authorities and officers acting in execution of this Act, or any directions or regulations issued as aforesaid." While the Act contains no specific reference to forcible entry under Section 42, yet under Section 17, which deals with power of entry in the case of nuisances, forcible entry is specifically warranted. Reading the above-mentioned Sections 17, 42, and 121 together, we can hardly conceive that any court would blame a local authority for making forcible entry if necessary in order to remove to hospital a patient certified under Section 42. It is obvious that, in the event of resistance, Section 42 would become a dead letter unless there were forcible entry and removal. The question, however, is more properly a legal one. (3) The local authority may make its own regulations regarding the management of its own hospitals, and these regulations may include the appointment of a medical practitioner as attendant on the hospital to the exclusion of other medical practitioners. The method of payment of the medical man appointed would not affect the question. In certain instances we believe that local authorities have made regulations for the treatment of patients in hospital by their private medical attendants.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Scotsman, Liverpool Courier, Grimsby News, Sheffield Independent, Birmingham Post, Hull News, Bradford Argus, St. Andrew's Citizen, Herald of Wales, Le Temps (Paris), Bury Guardian, Times of India, Pioneer Mail, Accrington Observer, Glasgow Weekly Citizen, Auckland Star, Architect, Cambria Daily Leader, North British Daily Mail, Goole Times, Builder, Norfolk Daily Standard, Journal des Debats (Paris), West Middlesex Herald, South Wales Daily News, Newcastle Journal, Rochdale Observer, Llandudno Directory, Eastern Morning News, Shrewsbury Chronicle, South Eastern Gazette, Manx Sun, Northampton Mercury, Preston Guardian, Liverpool Daily Post, Manchester Courier, Brighton Herald, Surrey and Hants News, Hereford Times, Yorkshire Post, Boston Independent, Kentish Express, Devon Weekly Times, Leicester Post, Portsmouth Times, Leamington News, Hampshire Telegraph, Leeds Mercury, Sussex Daily News, Woburn Reporter, Newport Advertiser, Luton Reporter, Bristol Mercury, Christian World, Sanitary Record, Brighton Gazette, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, City Press, Hertfordshire Mercury, Reading Mercury, Walsall Observer, Bradford Observer, Devon and Somerset Weekly News, Bristol Times, Ardrossan and Saltcoats Herald, Grantham Journal, Surrey Advertiser, Guernsey Star, Flintshire Observer, Surrey Comet, The Wilkes-Barre Record, Mail and Express (New York), Family Herald and Weekly Star (Montreal), Evesham Standard, Clifton Chronicle, Chester Courant, &c., &c.*
